Two Lectures

ON

THE ANÆSTHETISATION OF SO-CALLED "DIFFICULT" AND "BAD" SUBJECTS

Being the Emeritus Lectures on Anæsthetics delivered at the London Hospital on Nov 21st and Dec 5th, 1902,

BY FREDERIC W HEWITT, M.V O, M.A., M.D CANTAB,

ANÆSTHETIST TO HIS MAJESTY THE KING CONSULTING ANÆSTHETIST AND EMERITUS LECTURER ON ANÆSTHETICS AT THE LONDON HOSPITAL PHYSICIAN ANÆSTHETIST TO ST GEORGE'S HOSPITAL.

LECTURE I

Delivered on Nov 21st

GENTLEMEN,—Before I proceed to the consideration of the subject which I have chosen for these two lectures I should like to take the opportunity of expressing to the medical school of this hospital my best thanks for the honour that has been done me in appointing me to this newly created lectureship. I can assure you that it is a great pleasure to me to address you again. But I am even more gratified, if I may say so without being thought to be discourteous, by the actual creation of the appointment, for that creation clearly indicates the determination which is now apparent in most of our medical schools to train students more thoroughly in the administration of anæsthetics. My only regret is that the first Emeritus lectures on anæsthetics at this hospital have been entrusted to one who is so unworthy to deliver them. My successors will, I venture to hope and to predict, make up for my deficiencies

Although very few anæsthetics have been added to the list since ether and chloroform were first employed in practice there has been a steady development during the last 40 years in our systems and methods of anæsthetisation. The systems now in use have as their main object the safety and comfort of the patient, whilst the methods at our disposal are so numerous that whatever the special circumstances of a case may be a smooth and satisfactory anæsthesia may, with the rarest exceptions, be depended upon But whilst this development has been taking place in our systems and methods another development, not perhaps quite so obvious as the former, has been noticeable in what I may term the type of anæsthesia. The analgesic intoxication of former times has become gradually replaced by deeper and deeper anæsthesia. Little by little, in fact, the demands of surgery have increased, and in order to meet these demands a heavy tax has been imposed upon a section of the medical profession

The change in the type of anæsthesia to which I have alluded has had as its necessary consequence a change in the type of anæsthetist In the early days of chloroform and ether the medical man who administered an anæsthetic had as his sole object the prevention of pain. Even at the present day one occasionally meets a survivor of the old school who, having lived in some remote district for nearly half a century and having failed to realise the great change that has occurred in the type of anæsthesia, attempts to carry on a conversation with his patient in the middle of an abdominal section Formerly, any recalcitrant behaviour unconscious struggling movement, rigidity, embarrassed breathing pulse failure or undesirable after-effects were attributed to the patient not to the anæsthetist. The scope for skill in anæsthetising was thought to be so limited that nurses and even domestic servants were often entrusted with the administration When you leave your hospital you will find that if you administer anæsthetics at all in your practice your responsibilities will be considerably greater than were those of your predecessors Modern surgery demands the services of efficient anæsthetists even in simple cases and it is therefore, your duty whilst at your hospital to make yourselves efficient. The movement now on foot of thus providing for the greater safety of the public—a movement at last endorsed by the examining bodies—must be fostered and strengthened, for it deserves—nay, it commands—universal support. The death rate from anæsthetics—in other words, the risk a patient runs when he is rendered unconscious for a surgical operation—may be reduced to almost infinitesimal proportions, whilst the results of many surgical operations may be distinctly improved by placing the administration of anæsthetics in experienced and skilled hands Unhappily, there are still a good many leading members of our profession who either do not realise this fact, or if they realise it do not pause to consider its significance, and so long as this state of things obtains, even amongst a section of the profession, we cannot be surprised at the apathy displayed by the public concerning their own safety The opinions held by the laity regarding anæsthetics are almost ludicrous. They either believe that, provided their hearts are strong enough, they can take any anæsthetic with impunity, no matter who administers it, or they think that, the death rate of anæsthesia being incapable of reduction by skill and experience, they personally are pretty certain to be marked out by fate for a disaster during the operation about to be performed upon them. You will often find, even amongst the ranks of the educated classes, people who will haunt Harley street for a week with the object of settling whether they should or should not take a blue pill occasionally, but who will go to an unqualified and advertising dentist for the cure of toothache and cheerfully allow themselves to be dangerously asphyxiated by nitrous oxide or rendered pulseless by chloroform It would, of course, be going rather too far to say that every accident that now occurs is preventable, but there can be no doubt that in each year's death roll there are many cases in which life has been unnecessarily sacrificed.

What do we mean by good subjects for anæsthetics? I take it that by a good subject is meant a patient who, whatever anæsthetic we may choose, gives us no trouble during its administration, inhaling it freely displaying little or no excitement or inconvenient muscular spasm under its influence, passing quietly into deep anæsthesia without any respiratory derangement, remaining perfectly immobile during operations upon sensitive parts, and recovering with no unusual after-effects. Now a patient who behaves in this exemplary manner is entitled, I think, to be taken as a model and to be regarded, for our present purpose, as the normal type. I have on other occasions pointed out to you the common—and I had almost said the dangerous—fallacy of regarding the strong and perfectly healthy man as the normal and typically good subject for anæsthetics. He is by no means necessarily so I have also alluded to the popular fallacy of regarding strong cardiac action as essential for safe anæsthetisation, the fact really being that patients with comparatively feeble heart action are, *cæteris paribus*, better subjects than those whose hearts are perfectly normal and vigorous. The explanation is simple enough. Putting out of the question the presence of advanced cardiac disease, there is a correlation between the heart and the general muscular system of the patient, and the greater the development of the latter the greater will be the tendency for the patient to give trouble to the anæsthetist by muscular rigidity and consequent respiratory derangement. It hence happens that the comparatively feeble individual, as exemplified by the chronic invalid whose skeletal and cardiac muscles have undergone some degree of atrophy, passes quietly into deep anæsthesia. Speaking in general terms, therefore, it may be said that the patient with the "weak heart" is of the two, a better subject for an anæsthetic than the patient with the strong heart—a totally different doctrine to that which is generally accepted. As our normal or perfect type of patient for anæsthetics we may, therefore, take middle-aged women in moderately good health, of spare build sallow complexion, placid temperament, and moderate habits, possessing a free nasal air way and somewhat defective teeth. These are, in my experience, the best subjects for anæsthetics. No matter what agent may be chosen or what method of administration may be adopted patients of this type will in the vast majority of cases enter into, pass through, and emerge from anæsthesia without giving the slightest trouble.

As we depart from this the normal type of subject we begin to observe corresponding departures from an almost ideal anæsthesia. Younger women, for example, tend to display rather more muscular rigidity as they pass into deep anæsthesia, whilst the greater secretion of mucus and saliva may interrupt the smoothness of administration. Women who hunt or habitually take other forms of outdoor exercise will often give a little trouble to the anæsthetist, especially during abdominal operations. Elderly women, again, although good subjects, may be so susceptible to anæsthetics as to alarm an inexperienced anæsthetist, or, by reason of senile changes having taken place in their respiratory mechanism, they may not breathe as freely as younger subjects. Thus, a full dose of nitrous oxide free from oxygen administered to a thin woman from 70 to 80 years of age, whose chest walls have lost their elasticity, may readily lead to suspended breathing Anæmic, exhausted, and even emaciated patients are often remarkably good subjects for anæsthetics unless the anæmia or exhaustion be of acute origin or the patient has been in former times of powerful build, very obese, or of intemperate habits. Care is needed not to over anæsthetise such subjects.

Men are, as a class, not so satisfactorily affected anæsthetics as women, but young men approaching in type to what has been termed the normal give little or no trouble. When I come to discuss more particularly difficult and bad subjects you will find that most of the remarks that I shall make apply to men Children are generally said to be good subjects for anæsthetics and from some points of view this statement is correct Taking everything into consideration, however, I regard children as somewhat less satisfactory subjects than women of the type to which I have referred. A considerable time may be required to anæsthetise infants, the signs of anæsthesia are not always reliable, and when once the full effects of the drug have been produced great care is needed to avoid over-dosage. Children are certainly less liable than adults to give trouble from muscular excitement, and should suspended breathing take place remedial measures are comparatively easy of application, but the great liability in children to the free secretion of mucus, the frequency with which enlarged tonsils and adenoid growths are present, and the readiness with which vomiting occurs, not only in comparatively deep anæsthesia but after the administration, may, individually or collectively, account for difficulties Of all the patients one meets in dental practice the healthy school boy is most likely to suffer from nausea after nitrous oxide mixed with oxygen, whilst it is often difficult with such a to obtain the best results during an abdominal

What do we mean by difficult and bad subjects? I take it that under this heading may be included all patients who, unless skilfully treated, display marked excitement, rigidity, and a tendency, even though deeply anæsthetised, to inconvenient reflex phenomena, or, apart from the administration of an over-dose, pass into a dangerous state or actually die. I must again in this connexion impress upon you the fact that the patients whom we are now about to consider are not necessarily the subjects of any grave malady They are often, indeed, patients who have never had a day's illness. This is an exceedingly important matter and it is to my mind as interesting as it is important.

Difficult and bad subjects may be conveniently considered under six headings 1. Patients whose general health is good—possibly exceedingly good—but who possess some physical peculiarity rendering them more or less liable to intercurrent embarrassment or arrest of breathing 2 Patients whose respiratory tract is in some way encroached upon or whose respiration is in some way hampered by pathological or other conditions 3. Patients suffering from certain grave visceral or constitutional affections. 4 Highly nervous and excitable patients, those suffering from various nervous affections, and those who have become addicted to the excessive use of alcohol, tobacco, morphine, or other drugs. 5 Patients displaying in a state of combination or association the characteristics of two or more of the foregoing classes. 6 Patients who prove to be difficult or bad subjects without any discoverable cause.

1. The possession of a well-developed muscular system is often responsible for delay and difficulty in anæsthetisation, a fact which although applying particularly to men is not inapplicable to women. Vigorous and muscular men should, whenever possible, be anæsthetised by ether rather than chloroform. If the surgical requirements of the case call for the latter anæsthetic it should be given after anæsthesia has been obtained by the former The large number of fatalities from chloroform which have occurred in patients of this type should teach every medical practitioner a lesson. The explanation of such accident is to be found in one or other of the following considerations In the first place vigorous patients require larger doses of an anæsthetic than other subjects in order that muscular relaxation may be produced, the result being that the anæsthetist progressively pushes his anæsthetic and often pushes it too rapidly In the next place, such patients are more liable to excitement and struggling than others, so that during the stage of excitement intercurrent asphyxia from muscular spasm is liable to occur, and should it occur the chloroform vapour which has been imprisoned in the lungs is absorbed in dangerous quantities And, lastly, these subjects may give trouble from the presence of laryngeal mucus which in deep anæsthesia may actually cause arrest of breathing. Nitrous oxide and ether administered by a wide-bore inhaler produce admirable results in vigorous subjects, ether having a great advantage over chloroform in that it can be safely pushed till relaxation occurs A word of caution is necessary in dealing with the cases in which a change from ether to chloroform is effected. The change must never be made during any muscular excitement or struggling This stage should be allowed to subside, a cough encouraged, and the substitution then effected.

The symptoms displayed by patients during anæsthetisation are largely dependent upon the physical conformation of the upper air passages and particularly upon the number and arrangement of the teeth. Provided the nasal passages be wide and free breathing may take place wholly through the nose, and this state of things may be satisfactory so far as the anæsthesia is concerned. But in a large number of cases the nasal air way is either unavailable or inadequate and nature thereupon endeavours to force a passage through the mouth. In most cases she is more or less successful, but she often finds herself heavily handicapped owing to the teeth meeting one another very accurately, or to the swollen tongue pressing itself against them. The anæsthetist should realise the situation and assist nature in her endeavours by slightly separating the teeth by means of a mouth prop. Patients with large and overhanging upper teeth are specially liable to give trouble to the anæsthetist, for they tend to become very stertorous or to stop breathing altogether This is owing to the difficulty or impossibility in such cases of pushing the lower jaw forwards in order to bring the tongue from the pharynx. It is generally advisable with such patients to place a small mouth prop between the teeth either before the administration or soon after it has commenced. Long, irregular, and interlocking teeth are equally liable to fix the lower jaw and hence to favour occlusion of the air way Speaking generally oral breathing is to be preferred to nasal breathing, and it is especially necessary to secure it in patients with good teeth and powerful jaws. I have notes of several cases in which the neck was so thick and large as to obliterate completely the contour of the lower jaw, and in most of these cases I had some difficulty in keeping a free air way owing to it being next to impossible to push the lower jaw forwards in the customary manner Of late years I have in a large percentage of my cases inserted a small mouth prop between the teeth soon after consciousness has been lost, and I find that my results have been thereby improved The advantage of oral breathing over nasal breathing is, in fact, so great that I am almost inclined to advise you to use a small mouth prop in every case, inserting it rollerwise after consciousness has been lost and before the operation commences. Middle-aged men of powerful build, with red shiny cheeks, thick necks, and good teeth, require careful handling, especially during the induction of anæsthesia They belong to what may be called the "John Bull" type. They are best anæsthetised by administering a mixture of chloroform and ether (two of chloroform to three of ether) throughout, or by using this mixture up to the point at which the stage of rigidity begins, changing temporarily to ether, and continuing with chloroform. If the nitrous oxide-ether sequence be employed a mouth prop must be inserted before starting and a wide-bore inhaler used, any difficulties which may arise after the stage of rigidity has passed off being met by changing to chloroform. The advantage of the C E.-ether or the nitrous oxide-ether sequence over the continuous administration of the mixture or of pure chloroform is that the stage of rigidity and struggling may be nearly or completely eliminated I have anæsthetised a few patients of the "John Bull" type, in the sitting posture, for operations within the throat and I have found my resources somewhat taxed when hæmorrhage has been free. Such patients are also difficult subjects for abdominal section and particularly for such operations as thyrotomy for the removal of a laryngeal growth In one case, that of a powerfully built man who had had half his larynx removed on a previous occasion and who had then given me some trouble owing to the difficulty of keeping up deep anæsthesia by means of a Junker's apparatus, I administered a small quantity of morphine before the chloroform and obtained a very marked improvement in my results Obese subjects, if only obese, are not as a rule difficult to anæsthetise, but if the obesity be associated with such conditions as an inadequate nasal air way, perfect teeth, or a receding lower jaw, if it be grafted on, so to speak, to a previously well-developed muscular system, or if the patient be alcoholic or a great smoker, a good deal of difficulty may be experienced. As a general rule, the mixture of chloroform and ether administered slowly produces better results than ether or chloroform.

The commencement of an operation before perfect anæsthesia has been produced is in most cases unattended by anything more than inconvenient reflex movement. There is no conclusive evidence, to my mind, that the circulation is specially liable to be depressed by operating in moderately deep anæsthesia. But in certain subjects, and particularly in muscular and obese patients, the commencement of an operation during moderate anæsthesia is strongly to be deprecated owing to the reflex suspension in breathing which may result This particularly applies to rectal surgery I have notes of one case in which this reflex suspension of breathing seemed to be the starting point of an asphyxial condition which was with the greatest difficulty overcome. It is highly probable that this state has often been erroneously regarded as primarily cardiac. In heavily built and obese men, with flabby tissues and thick necks, any interference with free breathing may quickly lead to such swelling of parts within and about the upper air passages as to completely occlude them. Further clinical observation may perhaps enable us to state what traumatic stimuli are most likely to interfere with respiration during moderate anæsthesia The point is important, not so much in relation to fairly healthy persons, such as we are now considering but as regards patients who are dangerously ill and who cannot with safety be deeply anæsthetised Fortunately there seems to be far less tendency for such patients to respond either inconveniently or dangerously to the stimulus of an operation begun during partially established anæsthesia

---

An Address

ON

THE PROBLEM OF INFECTION AND IMMUNITY IN TUBERCULOSIS AND THE ISSUES INVOLVED.

Delivered before the West Somerset Branch of the British Medical Association at Taunton on Oct 31st, 1902,

BY SIR HUGH R BEEVOR, BART, M.D, F R C P LOND,

PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST PHYSICIAN KING'S COLLEGE HOSPITAL.

GENTLEMEN,—I thank you for the honour of the invitation to meet you and I crave your indulgence for my selection of so commonplace a subject for my address, but as this subject is equally interesting and important to us all I shall, I hope, gain your ready sympathy The revolutions in diagnosis, prognosis, and treatment of tuberculosis have been rapid, especially when attacking the lung, and it is to the lung that I shall devote my attention. However, it is not these aspects of tubercle upon which I would dwell, but rather upon problems which, while of long standing interest to our profession, have recently taken their place in the arena of the town hall and the county council chamber as subjects for public discussion. I refer to the problems of infection and prevention The public will be appealing to us for guidance and it is well that we should take stock of our knowledge and form a reasoned opinion. The cry is "Educate the public," and we are the educators

Let us presume that as their first lesson the public are learning the resolutions passed by the British Congress on Tuberculosis of 1901—viz., (1) that spitting in public should be suppressed, (2) that it is necessary to provide sanatoriums for consumptives, and (3) that they should do away with tuberculous meat and milk —a lesson in which we all heartily concur The first is a matter at least of simple cleanliness, the second is a judgment based upon ample experience worked out first in other lands, and as to the third the meat and milk are simply tested for their purity like any other food But we all recognise that it was not on such common general grounds that a congress was anxious to pass good resolutions it was upon one main ground—the fact that tuberculosis is now recognised as ranking among diseases which are infective diseases The educated public appreciate this and are asking, Is it not very infectious? This is what we have to answer and desire knowledge of, this degree of infectivity it is that we must state, the conditions of risk we must lay down, for it is our duty to consider our patients at least as much as their neighbours, and our patients will suffer, and suffer severely, if credited with an evil eye that is not theirs

Professor G Sims Woodhead has recently written, "Tubercle bacilli may become so modified that they can flourish saprophytically" Dr Kanthack stated that the organism of tuberculosis was capable of thriving outside the animal body, while Dr Sidney Martin stated that it had no independent existence. The variation of medical opinion, nay, in many cases the irreconcilability, upon the point of infectiveness, may be gathered from the words of speakers at the recent autumn conference at Berlin. From abstracts of their communications, representing medical opinions, I select the following quotations as evidence Professor Sangman protested that 'the utility of spreading among the public the fear of contagion by prescribing preventive measures such as partitions between each two persons sitting in offices and workshops as advised by Flügge is doubtful" Dr O Savoire, speaking of workshops, schools, and offices, said of curable and incurable tuberculous persons "they would in all cases, be separated from other people" Dr S von Unterberger wrote that "the contagion of tuberculosis in hospitals is not to be feared," while Director Gebhard stated that ' the homes for disabled consumptives will have to be built so that their neighbourhood is not a danger of contagion and that every danger is as much as possible removed from the persons in good health who frequent it or are employed in it." Dr O Denison said "To my mind the difference in importance is as 10 to 1 between the subject of susceptibility and immunity on the one hand and infection and virulence on the other", and to that point Dr Denison desired to direct the discussions

You will see that I am not tilting at windmills when I mention instances of the disabilities that are already afflicting some patients abroad. "In some parts of France they have had to abandon the idea of sending into the villages single patients of the working class, however strictly selected and although free from bacilli, for the peasants greatly fear tuberculosis, and for their cattle's sake, not for their own health." The Bethel (Sullivan County) board of health has adopted an ordinance imposing a penalty of 10 dollars for the first offence and 50 dollars each week, for entertaining a stranger or guest affected by tuberculosis other than immediate relatives or those dependent on the family Let us mark how the sufferers from this sub-infectious malady differ from those suffering from most infective diseases they are adults, not children, and the term of their illness may be counted by years, not weeks, moreover, as often as not, their powers of work are efficient If we had sanatoriums in plenty and funds to replace the earnings of bread winners it would not even then be necessarily right to follow the lead of the peasants of France or the board of health of Bethel. As we are not yet, however, sufficiently endowed with these aids, let us at least recognise that any exaggerated statement of the infectivity of tubercle will induce similar hardships in this country, together with other hardships consequent upon social taboo, whilst the ultimate result may well be an increase and not a diminution of tuberculosis

The present state of our knowledge may be, broadly, gathered from two regions (1) the region of biology, pathology, and comparative pathology, and (2) the region of experience in the present and the past, the incidence of the disease in man Now the evidence collected in either region cannot be said to conflict nor can it be said to coincide , it is conspicuously incomplete and links of association are evidently missing

In the field of biology one may briefly note tuberculosis of man, of bovine origin, of birds, and of fish Between bovine and human tuberculosis I shall not attempt to draw distinctions, however real may prove those differences which Professor Koch in 1901 impressed upon us and recently reiterated. Small though be the amount of transmissibility from cattle to man which Professor Koch admits even that is sufficient to give inherent probability to those experiences in America related by Professor Ravenel in 1901, and recently at the Berlin meeting by de Schweinitz and E C Schroeder, besides the recent results of Dr G Dean and Dr C Todd at the Jenner Institute, and it is sufficient to make us believe that bovine and human tuberculosis are convertible if not identical.

In birds avian tuberculosis we learn, is with difficulty convertible into the mammalian form in guinea pigs (Nocard)

From fish and slow worm cultures have been shown at the 1901 congress of great interest, as both had their origin in association with tuberculous sputa. In the fish the cultures were obtained from a carp found in a pond contaminated with tuberculous sputa , the slow worm had been previously infected with tuberculous sputa by Dr Moeller Now in either case a bacillus is found growing best at the low temperature of 22° C and not pathogenic to warm blooded animals. One would not think of associating it with tubercle but for the history If it be a transmuted tubercle bacillus its vagaries transgress the lines that usually mark specific difference, so that the discoverers would place it among the acid fast bacilli only and not name it bacillus tuberculosis These acid fast bacilli need not detain us, except one—the timothy grass bacillus. This will grow at the same temperature and produce the same lesions as tubercle, but Moeller its discoverer, finds by virulence and culture character that it is not tubercle nor is it convertible , the less initiated might well hesitate to class it. Other acid fast bacilli are of interest as pitfalls for the unwary who rely upon one or two bacilli as sufficient ground for a diagnosis—they come from butter, grass, manure, and other sources Thus we see that the tubercle bacillus no longer stands alone—it is one of a class widely spread in nature A classification of tubercle bacillus has been made Many students of morphology separate it from the bacteria, the class that provides most of our discovered infective agents, and place it with actinomycosis among the bacteriomyces—a step nearer the moulds. Our knowledge of the bacillus (as we will still term it) of tubercle outside the body has not advanced Coates has confirmed and extended Cornet s researches in dust , he did not find it in 10 dirty houses that had been for some years free from tubercle I have not come across other searches for it in a habitation supposed to be free from contamination

In pathology recent work has been mainly directed to determining the site of inception and to see how far a necropsy sustains the opinion that milk is the source of infection in children Judging from gross lesions the more advanced lesions of the mediastinal glands have been taken to suggest primary pulmonary infection in the vast majority of tuberculous children I think, however, that I see a desire to propound a theory where evidence cannot be forthcoming, a theory that bacilli may pass through a mucous membrane without breach of surface Seeing that the tonsil though not ulcerated yet may be supposed often to pass the bacillus on to the glands of the neck, I am inclined to support these theorists and to suggest that, after all, the early affection of the mediastinal glands may pass through the squamous epithelium of the œsophagus The inert bacillus requires a conveyance, the salivary corpuscles would suffice to carry the bacillus through the wall, stopping at the lymphatic gland , the gland most frequently affected in children lies on the œsophagus in the fork of the bronchi and trachea. I commend this view only for future testing but I am glad to find a particle of supporting evidence Mr S G Shattock last June showed primary tuberculosis of the œsophagus in a python. He remarked that in man it was only known by direct extension and was not primary but there was no lymphatic structure in the human œsophagus as in that of the python but most remarkable of all was his statement that infection had occurred by invasion between the cells of the epithelium which remained intact without any ulcer

The work of Professor Benda has made plain some of the puzzles that exercise our minds in the contrasts of acuteness and chronicity in tuberculosis The acute general tuberculosis and the tuberculous meningitis of general infection in children come, as it were, by anatomical accident Their acute symptoms are not apparently referable to any specially virulent strain of micro-organisms, but to the suddenness of their access to the blood stream. This access is from the frequently advanced disease of the mediastinal gland, which while being thoroughly permeated by advancing bacilli, is the final barrier—their next outlet is into the thoracic duct and blood stream. Like the power of a drug intravenously injected these toxins owe the acuteness of their symptoms to the fact that they travel directly in the circulation. Further, the bacilli make their home now on the walls of the blood vessels and so can continue to administer poison as rapidly as ever unless checked by thrombus formation Then in our conceptions of variety in virulence we must remember the varied path of extension. Another instance is the unfortunate experience, common to many of us, of a patient with phthisis who is rapidly improving but who is suddenly seized with a pleurisy that spreads over all the pleura, hampering respiration and pouring poison of tubercle into the system , this owes its source often to a mediastinal gland from which disease has had outlet to the pleura.

Comparative pathology I may only touch upon Nearly every other animal that dies in the Zoological Gardens gives, I believe, proof of its proclivity to tubercle and *per contra* I am not aware that any animal whose life was spent in a state of nature has ever been found to die from tubercle. Cattle, like children, have a special proclivity to advanced infection of the mediastinal glands—90 per cent. was the proportion of this lesion in a recent inquiry by Professor McSweeney The most interesting and striking evidence of contagion in cattle may be read in Professor Bang's successful prevention of the disease in calves by their segregation. The comparative virulence of bovine tuberculosis may be a factor in its spread, but the more simple explanation is the way in which cattle use their tongues upon their coats, their mangers, and their neighbours. What a dose they must take If we should feel alarm, taking the infection seen in European cattle to apply to ourselves let us take solace in the immunity of cattle in Japan which may as logically be applicable In any case we should avoid pressing analogy between animal and man too closely In cattle the veterinary surgeon applies tuberculin and he sees the cattle slaughtered So thorough and complete a view of the disease exposed to the eye of the pathologist cannot be exceeded. He can thus calculate with accuracy its prevalence, with the astounding result that roughly a million of the kine of Great Britain and Ireland are found affected. Besides milk containing bacilli we now know that the urine is often bacilliferous though there be no renal disease, and an enteritis may allow of vast numbers of bacilli being cast upon the ground. Many countries are trying to get free from the disease by the slaughter and isolation of cattle , some have desisted owing to the magnitude of the task. Victoria has had healthy herds to deal with and has been at work many years, but the extinction of the disease does not seem to be yet in sight.

Turning to the other region of our knowledge—our present and past experience of the disease in man—we find educated (that is to say, medical) opinion holds this view of infection, "Healthy persons run a distinct risk if the contact between themselves and the phthisical sufferers is close and prolonged." Instances of the risk occur to us , a few have been published from time to time. However, in 20 years so little evidence has come forth of the kind to be expected after the discovery of the bacillus that I think it probable that professional experience will, as a rule, agree with the experience of the observers in British sanatoriums who thought that they traced infection in 2½ per cent. of 700 cases No doubt the over estimate of the influence of heredity prevented any such view at all occurring to any but one or two medical men before our attention was aroused by Villemin and Koch.

I attempted to study past experience of a generation of phthisis in England a few years ago ; it was a simple voyage of discovery The returns showed that the amount of phthisis deaths varied with sex, with age, with general mortality, with place and time, food and air , the relation to all of these could apparently be traced but one could not trace infection Rural phthisis had been stated to be due to foci of infection, village infection , but if inquiry were pushed and one probed into parish records it remained untraceable. If we take the extra phthisis death rate of a county asylum as representing for the sake of argument a small epidemic, that will infallibly mark the phthisis rate of that rural union (not parish) as much heavier than any of its neighbours One could not find in ten year periods epidemics which would at all equal the extra rate due to the presence of an asylum. The amount of variation in the factors which I have mentioned was almost enormous For instance, taking sex—between the age of 10 and 15 years 200 girls die to 100 boys, taking time—then 40 years back those 200 girls would have been 500, and taking place either now or then—500 in Somerset would mean about 1000 in Northumberland. The place factor is really the overcrowded house, and the time factor is the food supply While not finding evidence of infection like that of other infectious diseases I allow that the conditions of the search would not detect so small a percentage as 2½ or even 5 but I believe that I am justified in saying that there is not the accidental rise or fall that would indicate chance infection as in other infectious diseases to an extent of 10 per cent —it might well be *nil* Is there any explanation why such evidence should not be forthcoming? It has been suggested by some writers that the latency of tubercle affords a solution of the problem There is a kind of latency (visible to the anatomist when he finds old cicatrices) which is common but very unequally distributed, being much more frequent in the old than it is in the young Now the frequency in incidence of phthisis is greater in the young, further, latency if it took the line of origin of other infective diseases would show the same rise and fall and therefore this theory affords no solution. The only kind of explanation to my mind is an inference which is not infrequently uttered, "We, all of us, repeatedly are exposed to infection"

Returning to our more definite experiences, while evidence of infection is in the main negative, evidence of immunity is of a positive character The prevention of phthisis taught us how to measure our ventilation and by that means afforded to the artisan a large extent of immunity That was 40 years ago, just at present we are realising from the sanatorium and by the expositions of Dr A. Ransome that by using a higher standard of ventilation a higher degree of immunity will be afforded. From 1865 to 1897 the mortality from phthisis in boys from 10 to 15 years of age fell from 100 to 32. During these 32 years no action was taken owing to any idea of infection, indeed, aggregation was increased by density of population and by school attendance to a three-fold extent and risks of infection must have increased accordingly Their diminished death rate was due to avoidance of malnutrition, of the infectious fevers and to a less degree to avoidance of bad air and faulty sanitation. Recently we have been improving our workhouse dietary, and still we have the "out-of-works as our most frequent patients Having on a former occasion[1] detailed much of this evidence I will not delay you by repetition. It is evident that the defensive powers of a healthy man can cope with the attacks of the bacillus, and these powers are infinitely greater in him with regard to tubercle than when they are placed in opposition to the attacks of the bacilli of other infectious diseases. In tubercle, therefore, the first aim should be to reinforce such defence by attention to nutrition, ventilation, and sanitation.

Let us consider next those persons whose contact with sufferers from phthisis is close and prolonged ("close" one considers an attribute of the room too small to ventilate well), are they to be considered unresponsive to the reinforcing of their defensive powers? Some unfortunately are so, but they are much less responsive to any other line of policy In speaking of these I am referring to the "submerged tenth.' Others are very responsive, such as inmates of asylums, and a policy of segregating these for tuberculosis which has been begun should be copied at all those asylums where there may be this close and prolonged contact of the unaffected with sufferers from phthisis, at the same time the standard of air-supply, food, and sanitation should be maintained. In workhouses similar tactics may well be pursued

We see how our attention has to touch on very many points necessary to achieve success in preventive measures. Accordingly our education of the public should be so broadly based that they may learn what are the conditions which make or mar healthiness of life. To effect this I would strongly recommend that the elements of hygiene be forthwith taught in our primary schools

There is a hiatus between the cultural experimental and dead house evidence of the working of the bacillus on the one hand, and our present and past experience of the incidence of the disease among our patients on the other In one case the life-history can be followed throughout and with precision the bacillus can be traced from point to point. In the other there is a fatal precision of death that marks so many attacks, but the bacillus is not traced.

We wish to deal with evidence, not theory, and there is usually no evidence upon the source of the infection according to our experience. It is open to one to argue that it is all of human origin, of bovine origin, or even derived from acid-fast bacilli of unknown powers of transformation.

> There are more things in Heaven and earth, Horatio,
> Than are dreamt of in your philosophy"

We do know this, however, that as the disease bears no relation to density of population outside the home itself, nor any relation to the frequency with which the healthy meet the sick (of which latter medical attendants and patients form a notable instance), therefore the disease is not infectious in the sense employed in speaking of the infective fevers. Then, I say, we shall be wise to utter no more than belongs to our own experience, ' healthy persons run a distinct risk if the contact between themselves and phthisis sufferers is close and prolonged." Those utterances abroad one is glad to find without parallel at home, yet here and there we see signs of our leaders in public health taking theory to work upon rather than experience.

I read a suggestion of a most admirable provision for dispensary, sanatorium, and hospital accommodation for consumptives at Liverpool. I would desire to see this scheme realised, for it is to a sanatorium especially that one looks as the great technical educator in the prevention of phthisis In this suggested scheme Dr Nathan Raw promises "that by isolating the incurable cases the municipality can largely prevent the disease.' From what I have already put before you I believe that such is not the present expectation—i.e., balance of probability And how greatly will a statement like that tend to procure the fulfilment of Dr Raw's own prophecy, ' In a few years it may be a matter of extreme difficulty if not an impossibility, for a consumptive to find ordinary means of employment." For his scheme Dr Raw finds that a halfpenny rate is necessary Many a ratepayer would gladly add to that halfpenny a sufficiency to replace the bread winner s earnings. Such an addition to the scheme I deem essential to its success Let us hope that Liverpool will never seek such avoidance of the sick as first prevents employment and then allows a consequent depletion of the sufferer's pockets, a depression of his spirits, and in the end a crop of tubercle in his impoverished family

And what are we to do in the future? For the cattle, plenty of fresh air, sunshine, and slaughter of visibly affected beasts —it is in this order that the chief inspector of Victoria proclaims his method If we essay complete prevention why not attempt it first in some limited area like the Isle of Man?

Among our patients we cannot fail to recognise how enormous is the proportion of the phthisis of to-day which exists in the lowest wage earner, the most ignorant of the poor Are we going to pillory the educated clerk for no risk or for an infinitesimal one, while these uneducated folk remain, whose potentialities for danger by whatever standard we may measure them, are infinitely greater and cannot be dealt with? If we do allow this we diminish the food or house room of a bread-winner and create the predisposition to tubercle in his family

The term 'infection" is too loose a term to apply to both measles and tuberculosis When its use does damage to the workman s prospects it is perpetrating an injustice upon him, ' sub-infectious" is a more proper term to employ in public health. By difference in the kind and mode of infection, and still more by the greater difference in resistance to the disease, our patients differ from cattle and the argument of isolation does not apply When we see the poor results in the isolation of infective fevers by hospitals for fever those who rank tubercle as most highly infectious must seriously doubt if it is a right policy to apply such a system to tubercle. No, we must proceed in the interests of all by education and attention to the wants of the people in food and in air, and we shall see the successes of the past excelled by the higher successes of the future

I earnestly hope that the medical profession at large will not encourage the public to avoid their tuberculous fellow creatures. Such a course will not, in my opinion, diminish the amount of tubercle. It will, however, infallibly swell the ranks of the unemployed, it will depress the phthisical wage earner's spirits, it will empty his pockets, and ultimately, by want and distress, reduce his family to that condition of low vitality which the tubercle bacillus requires for a successful invasion.

---

[1] THE LANCET April 15th 1899 p 1005 Brit Med. Jour August 1901 Catalogue of the Museum of the British Congress on Tuberculosis 1901

In conclusion, gentlemen, I would urge you, as the educators of the public in these matters, distinctly to let it be known that tubercle is not highly infectious. State that it is not a disease that requires isolation and that only under certain quite exceptional conditions does it appear to be infectious at all. Insist that healthy people enjoy extraordinary immunity, that fresh air and open windows are the great armour against its attacks, and that the instruction of the young in the general principles of hygiene will prove more valuable eventually than the isolation of the unwilling artisan or the excommunication of the clerk.

AN IMPROVED METHOD FOR THE MICROSCOPICAL DIAGNOSIS OF INTERMITTENT FEVER.

BY RONALD ROSS, C.B., F.R.S., F.R.C.S. ENG., D.P.H.,
LECTURER ON TROPICAL MEDICINE AT UNIVERSITY COLLEGE, LIVERPOOL;
WALTER MYERS LECTURER AT THE LIVERPOOL SCHOOL OF
TROPICAL MEDICINE; LATE MAJOR, I.M.S.

IN the Harben lecture, delivered at King's College, London, on Nov. 10th, 1902, I described in detail the method referred to in this note[1], but as the matter may be of interest to a large number of practitioners I think that it would be advisable to publish a brief description of it here.

There are at present two methods in universal use for the detection of the parasites of malaria. Both consist in spreading out over a large area a small quantity of blood. In one method the blood is examined in a liquid state and in the other it is dried. In both cases about one cubic centimetre of blood is spread out over about four square centimetres of area, so that the film of blood is a very thin one. This attenuation is necessitated by the fact that a thick film of blood is too opaque to permit of the easy detection of the parasites through the mass of hæmoglobin. Unfortunately, the attenuation, though required for the reason mentioned, has one great disadvantage—namely, that if the parasites are scarce we are compelled to search in many fields of the preparation in order to find them, and it is obvious that the number of fields which we must examine varies directly with the scarcity of the organisms.

It has long occurred to me that we should be able to detect the parasites in a thick film if only we could succeed in treating the blood in such a manner as to do away with the obscuring effect of the massed corpuscles. The method which I adopt for this purpose depends upon the fact that the parasites, even the smallest of them, adhere to the stromata of the corpuscles which contain them, so that, as long as we retain these stromata we retain the parasites. Now the opacity of a thick mass of blood is due, not to the stromata of the corpuscles, but to their hæmoglobin and it is easy to wash out this hæmoglobin without washing out the stromata, either in a dried film of blood or in a dilution of blood.

I have tried numerous variants based upon these considerations, but I select the following as the simplest and easiest for general adoption. The finger is pricked by a lancet-shaped needle or by the point of a lancet. A large drop of blood, amounting to, say, 20 cubic millimetres, is taken up on the glass slide or cover glass and is *slightly* spread out by means of the needle or lancet—that is, it is spread over an area which can be covered by an ordinary cover glass. It is then allowed to dry either naturally or over a flame (without heating so much as to fix the hæmoglobin). The result is that we have a thick dried film of blood in which about 20 cubic millimetres of blood (instead of the one cubic millimetre generally used) are disposed over an area which is not larger than the area of blood usually examined by the ordinary processes. As soon as the film is perfectly dry I lay upon it by means of a glass rod a quantity of aqueous eosin solution sufficient to cover the film of blood. The solution is the one which is usually employed in order to obtain the Romanowsky effect. It is allowed to remain upon the film of blood for a period up to about a quarter of an hour. This period should be inversely proportionate to the strength of the solution. As the film of blood has not been fixed the solution of eosin will take out the hæmoglobin of the dried corpuscles and, at the same time, will stain the residual mass consisting of the stromata of the corpuscles, the leucocytes, blood plates, and parasites. After the solution has remained upon the film for the period required it is washed off by a very gentle stream of water. As the film has not yet been fixed to the glass it is most essential here to use no strong current of water, or else the whole of the residual mass will become detached from the surface of the glass. As soon as the eosin solution has been washed out a weak solution of the methylene blue which is employed for the Romanowsky stain is allowed to run over the film, just as was done for the eosin solution. The blue is permitted to remain only for a few seconds, the time varying inversely with the strength of the solution. Especial care must be taken not to stain the preparation too dark a colour. Next the blue is washed off very gently in its turn and the preparation is complete. We can now dry the stained film and mount in Canada balsam, or examine it directly by placing a drop of cedar oil upon it for the immersion lens, or we can mount it in water, place a cover glass over it, and examine as usual.

The preparation will differ from those in ordinary use in two particulars; first, it will contain no hæmoglobin and will consist only of the transparent stromata of the corpuscles, the leucocytes, blood plates, and parasites; and, secondly, 20 times the amount of blood used in an ordinary preparation will now be found disposed over the area covered by the cover glass. From this it follows that we shall find 20 times as many parasites in each field of the microscope as would be found in an ordinary preparation of the same blood; in other words, we may say that these preparations will have 20 times the diagnostic value of an ordinary preparation. If the Romanowsky stains are efficient the smallest parasites will be seen scattered over the field as small blue rings with a deep crimson dot within or upon the ring, this dot being, of course, the nucleus. If the preparation has not been over stained the pigment of pigmented parasites will also be visible. I make two preparations—one stained by the method described above and one in which the hæmoglobin is simply washed out with water. In the latter the larger pigmented parasites are very easily visible, owing to their pigment, without any staining at all.

Dr. J. W. W. Stephens, formerly of the Malaria Commission of the Royal Society and now of the Liverpool School of Tropical Medicine, kindly tested these methods for me by making comparative numerical counts of the parasites found respectively in a preparation made in the old way and one made in the new way, both from the same patient at the same time. In an ordinary liquid film of blood he found 15 parasites during five minutes' search. In a dehæmoglobinised thick film preparation of the same blood stained by the above method he found no less than 76 parasites in one minute, showing that, this preparation was 25 times better for diagnostic purposes than the former preparation. In a single field of it he counted no less than 70 parasites. In another case in which only one crescent was found in several ordinary specimens after long search I discovered five in five minutes in a dehæmoglobinised thick film preparation (unstained).

It is necessary to add that the student should familiarise himself with the appearance of the parasites in this kind of preparation. He had better practise at first with cases containing considerable numbers of organisms.

I have experimented on dehæmoglobinised dilutions of blood, "centrifuged" so as to drive down the residual stromata to the distal end of a capillary tube, but cannot say that the result is better than that given by the very simple method described above.

Skilled students have long been accustomed to search for the larger parasites in the thick edges of liquid films. I have used dehæmoglobinised thick film preparations for finding crescents since 1895, and Manson employs them for staining flagellate bodies; but I do not think that the facility with which we can detect the smallest parasites in such specimens when properly stained is generally recognised.

Liverpool.

VACCINATION RASHES AND COMPLICATIONS[1]

BY GEORGE PERNET, M R C S ENG, L R C P LOND,
ASSISTANT TO THE SKIN DEPARTMENT UNIVERSITY COLLEGE
HOSPITAL LATE PATHOLOGIST TO THE HOSPITAL FOR
DISEASES OF THE SKIN BLACKFRIARS LONDON

AT a time when we are passing through an epidemic of small pox, and when large numbers of individuals are being vaccinated and revaccinated, I have thought it would be opportune and interesting to review shortly the subject of vaccination rashes and complications In dealing with this matter I have no fear of supplying weapons to those who oppose the practice of vaccination. It is the function of a science of observation like medicine to record carefully and impartially all phenomena, normal or otherwise, that we may thereby increase the sum of our knowledge and the usefulness of our art. It is not my purpose in this paper to discuss the value of vaccination—that is a point I take it, upon which we are all agreed I would merely remark that the advancement of all knowledge is a process of slow and laborious evolution I mention this because it is the stereotyped fashion in some quarters to make much of the fact that Jenner expressed the opinion that vaccination absolutely protected against small pox. We are wiser now and know that vaccination in infancy does not confer complete immunity It must not be forgotten, however, that small pox itself does not absolutely protect an individual against a second attack, any more than one attack of herpes zoster excludes the possibility of a second, although in both diseases it is extremely rare for two attacks to occur Louis XV of France is said to have had variola at the age of 14 years but that did not prevent him dying from a second attack at the age of 74[2] Again, there can be no doubt that cases of syphilitic re infection have occurred. As far as Jenner is concerned I may be permitted to say that his original contributions are models of lucidity and honesty of purpose and breathe the spirit of Harvey s noble ' De Motu Cordis "

It will add, I think, to the clearness of my remarks if I adopt the following division of the subject, suggested originally by Dr T Colcott Fox,[3] which is at once simple and natural, according with the manifestations as they present themselves clinically (1) local abnormalities or irregularities in the development of the vaccine vesicles, (2) incidental exanthematic eruptions, (3) diseases inoculated with vaccinia at the time of the operation, (4) diseases of a septic nature which find a nidus in the wounds subsequently to the operation, and (5) diseases excited in subjects specially predisposed to the same. To which I will add—(6) accidental vaccination, (7) horse pox or grease and sheep-pox in man, (8) effects of intercurrent diseases on vaccination and *vice versâ*, and (9) vaccination as a mode of treatment.

1 Among the local abnormalities extra vesicles sometimes occur due probably to the movements of the child and more points being inoculated than was intended. At other times bullæ may form instead of vesicles (vaccinia pemphigoides) In the case of calf lymph this arises as far as I can ascertain from impotent lymph. The bullæ leave no scars In such an event vaccination should be done over again with good lymph. Jenner referred to this as ' spurious ' cow pox and pointed out that it was not protective. He insisted on the necessity of re inoculation with the proper virus[4] Again vesicles may be retarded in their development or may not form at all In connexion with the late appearance of vesicles curious instances of delay have been recorded two months (Brierly[5]) one year (George Harley[6]) But the most remarkable was a delay of 14 years, recorded by no less an authority than Sir Thomas Watson The patient was a girl 14 years of age who had been vaccinated in infancy In the course of an attack of influenza vesicles developed on the old vaccination areas and, what is more, an elder sister was revaccinated with the lymph of the aforesaid vesicles with positive results[7] There are also curious instances of revivification of old vaccination areas as a result of revaccination or a subsequent attempt at vaccination where the first had failed In some cases instead of drying up in the normal way, the vaccination areas may go on to ulceration with induration of the base and exudation, forming crusts accompanied by axillary adenitis Such a condition might give rise to the erroneous diagnosis of syphilis These ulcers have been called chancriform by the French. In one instance Leloir and Hervieux investigated an epidemic of this kind 37 out of 38 children being affected The lymph was of human origin, but no specific symptoms developed.[8] Gangrene has also been observed as a local complication. Diday has recorded the growth of hair as a result of vaccination forming a coronet round the areas[9]

There has been some discussion in the journals with regard to relapse of vaccination.[10] If by that is meant a formation of typical vesicles going through a normal course and following on a successful vaccination I have never seen such a thing. But I have seen swelling up of one area (out of three) commencing a few days after the shedding of the scabs after successful vaccination. The purplish red lesion was of the diameter of a sixpence, flatly raised at first but becoming convex. It felt soft in the centre, but on making a puncture no fluid escaped, the contents being jelly-like Under treatment (europhen and blue wool and collodion) it gradually flattened down leaving (three months later) a slightly raised scar[11] There was no axillary adenitis I could only put this complication down to the staphylococcus The patient had probably inoculated the area with her nails, and this was the more likely as he had a few acne pustules about the chin. In a case under the care of Mr F Gower Gardner of Warwick, small red spots appeared after successful revaccination and gradually enlarged to the size of the vaccinated areas[12] Hypertrophic scars may develop on vaccinated areas[13] Such a condition is sometimes recorded as keloid but it is important to bear in mind the differences between true keloid and hypertrophic scar

2. As to the incidental rashes some occur early They are usually urticarial or erythematous and are in most cases evanescent, but they may also be vesicular and even bullous As to the last named in infants and young children, the possibility of impetigo contagiosa bullosa must not be lost sight of especially when there are only a few bullæ irregularly scattered about one limb or the face A fairly common condition is the so-called vaccine lichen, consisting of a number of pin point, red conical papules which come out in crops and may affect many parts of the body According to Dr H. Radcliffe Crocker, the rash comes out from the fourth to the eighteenth day, usually about the eighth.[14] The character of the eruption is in some cases papulo-vesicular, exceptionally it is pustular This kind of rash had apparently been noted by Jenner More rarely still the groups of small vesicles may run together forming bullæ, but this is a rare occurrence As a rule it soon subsides but in other cases it may be very persistent The same may be said of urticaria following vaccination The fact is that urticaria once started is sometimes difficult to quell. Erythema multiforme may also ensue, no doubt as a result of a toxæmia, the rash appearing as papules about the backs of the hands and face, or it may take the form of an erythema iris[15] or erythema bullosum These conditions may occur when the vaccination areas are nearly or quite healed. Impetigo contagiosa is not uncommon in neglected children and many parts of the body may be involved by

bacillus tuberculosis from phthisical sputum, &c., may occur is an ascertained fact, but it is not an easy thing to produce experimentally As far as vaccination is concerned it is very difficult, as Dr Colcott Fox rightly points out [31] to exclude the possibility of pre-existing bacilli having found a suitable soil in the wounded tissue or of a secondary infection from the outside.

Vaccination has also been accused of leading to an increase of leprosy Now, although leprosy is undoubtedly a contagious disorder, all attempts to inoculate the disease in sound individuals have failed. Danielssen and others have tried it on themselves and on various persons who have voluntarily submitted to the test The case of the Hawaiian criminal Keanu, inoculated as an alternative to death, is not decisive, as leprosy occurred in some of his relatives and the disease being moreover, very prevalent in the Sandwich Islands, he may have contracted it in another way The long latency of the complaint is a factor which makes it difficult to arrive at a positive conclusion in countries where the disease is endemic and in the case of individuals who have lived in those countries The source of error afore mentioned is a valid objection to the very few published cases of so-called vaccinal leprosy The careful inquiries of the Leprosy Commission in India on this point led the commissioners to report that the practical danger of leprosy being diffused in this manner was minimal, even supposing the disease to be highly contagious.[32] Arning and Auché and Carriere have found the bacillus in the vaccine vesicles of lepers so that the possibility of transmission in arm-to-arm vaccination in this way cannot be denied. But Armauer Hansen who originally discovered the bacillus lepræ and whose authority on any subject connected with leprosy is acknowledged, cannot believe that such transmission could have been frequent as some writers have contended. Further Hansen distinctly states that in Norway leprosy has steadily diminished during all those years in which vaccination has been compulsory In 1891 he put the question to all medical men in Norway who had anything to do with leprosy and not a single one had ever observed such an occurrence.[33] As the leprosy bacillus has not yet been either cultivated outside the human body or successfully transmitted to animals calf lymph cannot be accused of being a cause of leprosy

4 I have next to consider diseases of a septic nature which find a nidus in the wounds subsequently to the operation This portion of my subject and the one just dealt with overlap to some extent. Given strict cleanliness and carefully prepared lymph nothing but the vaccine virus should be inoculated at the time of the operation. Erysipelas is a rare complication. It varies in degree and may remain more or less localised to the neighbourhood of the vaccinated areas On the other hand it may spread extensively and sometimes prove fatal. Jordan[34] has called attention to the fact that erysipelas may result not only as a result of streptococcal, but also of staphylococcal, infection. Erysipelas may develop in a vaccinated child as a result of erysipelas in the mother or in a neighbour coming in contact with either the child or its parents Furunculosis, cellulitis and even septicæmia and pyæmia have been observed Impetigo contagiosa and gangrene have already been alluded to A very rare complication is tetanus. Dr W Findlay and Dr J W Findlay [35] have recorded a case of this kind following vaccination on the leg occurring in a woman aged 21 years They have further been able to collect ten other cases Of these, Toms's case followed calf-lymph vaccination on the arm, and another is recorded in the report of the Royal Commission on Vaccination in which human lymph was used. This is an interesting point Tetanus is caused by a bacillus found in the earth and *a priori* might be expected to be common in calf lymph owing to accidental contamination. But tetanus as a complication of wounds is an extremely rare condition, in this country at least, and Dr G Vivian Poore,[36] who has made inquiries, found that in the market gardens of the Thames Valley it was the rarest of diseases This agrees with the rare occurrence of tetanus among agricultural labourers

I may here refer to vaccination on the leg, demanded by some ladies I have vaccinated very few in this situation, but in one case the patient, instead of keeping quiet, took off the protective dressing put on coloured stockings in direct contact with the unhealed vaccine areas, and went to a ball. The result was a great deal of local inflammation, with the formation of a large irregular bleb full of sero-pus The patient was quite sure that it was the vaccination.[37]

5 An interesting part of the subject under review is the fact that diseases may be excited in individuals specially predisposed to the same. Here again, the *post hoc* fallacy crops up. Nevertheless, vaccination appears to have started psoriasis where there was a predisposition, but that it was actually the cause is another story Occasionally, one or more psoriasis lesions may precede the vaccination and sometimes too, rashes have broken out when vaccination has been postponed which would inevitably have been ascribed to the latter had it been carried out In a similar way an eczema may be started by vaccination. In two recent cases vaccination led to the recurrence of a cured eczema. In infants vaccinated very early in life, before congenital syphilis has developed, the specific symptoms would appear to the lay mind to be the result of the inoculation with lymph. It must be remembered, too that the subjects of hereditary lues do not always present the "old man" appearance but may at first look healthy enough I have lately seen pityriasis rosea occur in a recently vaccinated patient sent to me by Dr Percy J Edmunds, but there was no reason whatever to think that there was any connexion between the two conditions.[38] The sequence was, no doubt, quite accidental.

6. There are numerous instances of accidental vaccination scattered up and down in medical literature. I have seen it on the face and wrist. Medical men have inoculated themselves on the lip through the small wound caused by the broken end of a capillary tube whilst blowing out the lymph. When it occurs about the mouth or cheeks it gives rise to much discomfort, as may well be imagined, especially as regards opening the mouth. I have seen an interesting case in a woman nursing her vaccinated child, the accidental vaccination occurring on the cheek as the result of a scratched pimple. She had never been vaccinated, as her parents objected to the practice [39] Dr A. MacLennan [40] has recorded the case of a man in whom the chin was inoculated He thought that he got it off a towel used by other members of the house, five of whom were vaccinated The patient himself had declined to be vaccinated as he did not think it necessary Accidental vaccination in the great majority of cases occurs as a single lesion giving rise at a certain stage to much surrounding redness together with swelling and tenderness of the corresponding lymphatic glands. But Dr Arthur J Hall [41] of Sheffield has published a case in which there were 11 lesions about the dorsa of the hands The patient was a domestic servant who had never been vaccinated and who suffered severely at the time from chapped hands The vaccinia was contracted from a recently vaccinated baby she had nursed. When the lesions are single the possibility of an extra genital primary syphilitic sore may arise in the observer's mind, especially in certain stages of such accidental vaccination. The scar left by an accidental inoculation in the lip, for instance, may also be taken for the remains of an old primary syphilitic sore, especially if the patient be the subject of syphilis.

7 Much of what I have just said applies to the accidental inoculation of horse pox or grease Men looking after horses with greasy heels may contract the disease about the hands or forearms and also on the face This fact was well known to Jenner who held the opinion that such individuals, employed in milking transmitted the disease to cows giving

the planting out of micro organisms by the nails It was evidently observed by Jenner[16] Where the lesions are numerous with much crusting it looks very formidable, and it is just such cases that have helped to make people prejudiced against vaccination, although vaccination has had nothing to do with the rash directly Eczema is a common complaint in babies and is frequently seen in those who have not been vaccinated But unfortunately with the public all skin eruptions that occur after vaccination are put down to the latter on the fallacious *post hoc propter hoc* principle

A more important but uncommon eruption is generalised vaccinia, a subject about which there has been much discussion as to whether it arose from auto inoculation or was conveyed through the blood When an irritating rash is present on the body at the time of the vaccination auto inoculation can account for the generalising of the vaccinia. On the other hand there are cases which appear to be in favour of the other view, which has many supporters in France Jenner[17] records instances where pre existing pimples and vesicles were converted into vaccinia pocks which kept pace with those on the arms in their progressive changes and further, which is an interesting point, afforded a perfect vaccine virus[18] Woodville in his account of his experiments records a number of instances in which patients developed a generalised eruption which resembled small pox This was quite contrary to the experience of Jenner, who concluded that the rashes described by Woodville had not been produced by the pure, uncontaminated cow pox virus, but that they might be explained by the fact that Woodville had inoculated a number of his patients with variolous matter on the third or fifth day after the vaccine had been applied and used lymph thus obtained for further cow pox inoculation Chauveau has shown that a general vaccine infection was possible by inducing an artificial general horse pox as it were in the horse by injecting the vaccine virus into the trachea and veins[19] In connexion with the subject of generalised vaccinia the interesting experiments of Bryce and Hicks may be alluded to They found, when a second vaccination was performed on a patient a few days after the first inoculation, that, assuming the latter to have been effectual, the second vesicle, in the words of Hicks, made immense strides to overtake the first.[20] Further, that admirable observer, Trousseau, has recorded a case of generalised vaccinia in which 27 vesicles exactly like vaccination vesicles[21] developed about the face, trunk and limbs on the eleventh day after vaccination in eight places Trousseau concluded that the rash was the result of auto inoculation, especially as the child had a fine sweat-rash at the time of the operation This led Trousseau to go on revaccinating subjects from day to day, from the fourth day onwards after the primary vaccination He found that after the ninth and sometimes the tenth day the inoculation was unsuccessful and that the earlier the re inoculation the more typical were the vesicles[22] With regard to auto inoculation the eyelids may become affected (vaccinal blepharitis) and lead to what Saemisch has called a vaccine-ophthalmia with keratitis[23]

Vaccinia gangrenosa is another very unusual condition Mr J Hutchinson[24] has described a case in which on the eighth day after vaccination a papulo-vesicular eruption appeared on the trunk which rapidly assumed a sloughing character The vaccine vesicles were unaffected Mr Hutchinson looked upon it as a true vaccinia passing on to a gangrenous condition and analogous to varicella gangrenosa. Sir William Stokes has recorded a case in which 48 hours after vaccination, purple and black spots appeared on the body, followed by gangrene The vaccine areas themselves were unaffected, and other children vaccinated with lymph from the same source exhibited no rash of any kind[25] This appears to have been a purpuric condition originally, but a "pemphigoid" rash is mentioned in connexion with the case, so that it may have been a hæmorrhagic bullous eruption I may add that the bacillus pyocyaneus has been isolated in dermatitis gangrenosa infantum, and moreover bullous eruptions have been observed in infections by that micro-organism. Bullous eruptions and a somewhat rare condition, dermatitis herpetiformis, have followed vaccination

I should like to say in passing that the inoculation of small pox in the human subject is now a misdemeanour, although at one time in this country so great were the ravages of small pox that it was considered an improvement to go through an artificially induced variola

Morbilliform and scarlatiniform rashes also sometimes occur, but they give no trouble Purpura is an extremely unusual eruption It may appear as minute punctiform hæmorrhages or the condition may be much more serious with extensive hæmorrhages into the skin, accompanied by febrile symptoms, epistaxis, hæmaturia, together with hæmorrhages into the vaccination vesicles, indicating profound changes in the blood or perhaps, in some cases depending on hæmophilia.[26]

I have seen the itch ascribed to vaccination as the rash appeared soon after the latter, but the discovery of the acarus exposed the fallacious reasoning of the patient

3 I now come to diseases inoculated with the vaccine virus at the time of the operation—a very important matter indeed and one which has led to no end of controversial writing on the part of opponents of vaccination I propose to deal in this part of my paper with syphilis, tuberculosis, and leprosy As to the first, there is no doubt as to syphilis having been communicated to healthy children and adults by means of vaccine lymph derived from congenitally syphilitic infants Instances of this unfortunate accidental syphilisation were faithfully recorded by medical men immediately they recognised them I need hardly point out that cases of the accidental mediate inoculation of syphilis occur from time to time quite apart from vaccination When the possibility of such an accident in vaccination became known the medical profession was on its guard Dr Radcliffe Crocker states that at the East London Hospital for Children, where the patients were the poorest of the poor, over 20,000 cases passed through his hands and he never saw a case of vaccinal syphilis, nor did any of his colleagues there, or he would certainly have heard of it Dr Colcott Fox has had a similar negative experience at another children's hospital[27] Now that calf lymph is in general use, inoculation of syphilis *vià* the lymph is a thing of the past It must not be forgotten, however, that in a certain stage of syphilis the blood of the patient is virulent and that an unclean lancet charged with such blood may be a source of danger in vaccination. Jullien has recorded a recent instructive instance of two surgeons contracting syphilis through wounds of the fingers whilst operating on a syphilitic woman just before the appearance of her secondary rash[28]

With regard to tuberculosis a number of investigators have looked in vain for the tubercle bacillus in the vaccine vesicles of phthisical patients and animal inoculation experiments with lymph from that source have been negative Now that human lymph has been given up the possibility of tuberculosis being conveyed from calves must be examined In the first place, tuberculosis in calves is very rare, but nevertheless the plan adopted in Belgium of making a necropsy of the animal immediately after the lymph has been collected is a sound one[29] The selection of vaccinifer calves should also be carefully made and animals having any sign of disease should be rejected Chauveau and Jusserand failed to produce tuberculosis in guinea pigs with lymph obtained from a tuberculous cow[30] Another element in the discussion of this subject is the opinion expressed by Professor Koch at the British Congress on Tuberculosis in 1901 that bovine tuberculosis was not communicable to man That inoculation of the skin by the holder, a plan originally recommended by Mareschal, a French army surgeon (*vaccinostyle individuel*), will be found useful After vaccinating a patient the pen is thrown away and a fresh one used for the next case.

A SECOND CASE OF SUCCESSFUL OPERATION FOR PERFORATION IN TYPHOID FEVER[1]

By ANTHONY A. BOWLBY C M.G , F R C S Eng ,

LECTURER ON SURGERY AT ST BARTHOLOMEW'S HOSPITAL.

THE patient was a boy, aged 10 years, who was admitted into St. Bartholomew's Hospital under the care of Dr Norman Moore on Sept 1st, 1900 He was in the third day of an attack of typhoid fever and beyond the fact that the case was severe and prolonged it called for no special comment except that after the temperature had come down to normal on the thirteenth day he suffered from a severe relapse on the twenty first day and had again a very high temperature, reaching 105 4° F on one occasion The date of the relapse was Sept. 19th. On Oct. 1st the temperature was still above normal (101°) and tympanites, which had been present throughout, was still well marked. There was also some crepitation at the bases of the lungs On the 2nd, after a slight shivering fit, the patient became blanched and cold, the temperature sinking to 97 6° but there was no subsequent evidence of hæmorrhage or pain On the 3rd he seemed to be better but the temperature was still 101° The abdomen was less distended and the bowels acted without enemata On the 4th the temperature was normal but the abdomen was again distended The pulse was 96 A little before 3 P M. he complained of some difficulty in micturition and while passing urine he was seized with severe pain in the abdomen The temperature half an hour earlier had been 102 6° but after the attack of pain the patient sweated profusely and it dropped to 98° For the next half hour the boy was screaming with pain and was exceedingly restless He then became quieter and collapsed, with sunken eyes, a cold sweat, and shivering The pulse had gone up meantime to 140 I saw him at 4 30 P M. with Dr Norman Moore and found his general condition to be as above described The abdominal wall was hard and fixed during respiration and I agreed with Dr Norman Moore that perforation had almost certainly taken place and quite concurred in his proposal that an operation should be undertaken at once At 5 P M therefore, two hours after the symptoms of perforation, the abdomen was opened in the middle line and at once free gas was found in the peritoneum. A considerable quantity of almost clear fluid welled up but there was no large collection of fæcal matter The intestines were so much distended that several coils had to be allowed to extrude and they were kept wrapped in hot towels Many areas of inflamed peritoneum indicated the affected Peyer s glands I then sought for the cæcum and after finding it I rapidly passed the small intestine through my hands till I found a perforation situated less than two feet from the ileo-cæcal valve. The bowel was not adherent or otherwise altered nor could any induration be felt in its walls, but the peritoneum corresponding to the shape of a Peyer s patch was very red and injected The opening in the intestine was quite small, being not much larger than a pin s head. I wiped the bowel clean and then closed the opening by five Lembert s sutures of fine silk. The greater part of the incision was now closed and a glass drainage-tube was placed in its lower end Owing to there being no complications the operation was completed in about 20 minutes and at the end of it the patient s general condition was none the worse for the handling and exposure of the bowel. The peritoneum was not douched but the intestines were carefully wiped clean and all fluid was completely mopped up from the pelvis and elsewhere with sponges For several days the boy remained very ill and in the early morning after the operation the pulse was still 150 the temperature being 100 4° There had been no sickness and flatus was passed. The patient was fed by nutrient enemata and only a little water or ice was given by the mouth. The abdomen remained distended After this time there was steady and rapid improvement except for some sickness on the 7th and a troublesome cough, so that by the 10th (six days after the operation) the boy seemed to be convalescent. On that day, however, he had a slight epileptiform attack and in the evening a more severe series of fits necessitating the administration of chloroform. This threw him back and weakened him but he again rallied and in spite of a return of severe convulsions on the 20th he ultimately recovered The tympanitic distension of the abdomen which had been so marked throughout continued till the end of his illness I saw the boy some months later and found him to be in excellent health

I have already recorded a similar case of operation for perforation of typhoid ulcer in vol lxxx. of the Transactions of the Royal Medical and Chirurgical Society (in conjunction with Sir Lauder Brunton) and in that case also, which had a similar satisfactory ending, the patient was operated upon late in an attack of typhoid fever, for he was in the sixth week of the illness and was at the time suffering from a relapse. In that case there were much induration of the perforated Peyer s patch and some consequent difficulty in suturing the aperture, but in all other respects the cases had much in common except that at the time of the operation the boy whose case I now record was much more ill than was the first patient and that there was greater distension of the abdomen

The two cases represent the only patients I have operated upon and there can be no doubt that they represent two lives saved. On the other hand however, I do not regard them as at all typical cases of typhoid perforation but rather as typical of a special class in which perforation occurs after the fever is practically over and in which the general condition of the patient is otherwise relatively good. In such patients as these the symptoms of perforation are generally well marked and the diagnosis is readily arrived at But in very many other cases the reverse is true, for it not infrequently happens that the perforation occurs when the fever is yet high in patients who are nearly or quite unconscious and in whom there is no perception or expression of pain and who may have distended and tympanitic abdomens before perforation occurs Many such patients are already at death's door and in not a few of such cases in addition to the perforation there are numerous other areas where the intestine is so rotten that its giving way is only a question of time It is not to be supposed that even if an ulcerated bowel is sutured many such patients can recover and in some of them at least the operation of suture may be practically impossible I saw at least one such case in South Africa with Dr H H Tooth in which the patient was quite unconscious and manifestly dying Dr Tooth suspected that there might be a perforation but as the symptoms were not clear no operation was undertaken and the same day the man died. A post-mortem examination showed that the intestine was so matted and adherent to the peritoneum and mesentery that even after death it could with difficulty be unravelled and though there was a perforation I do not think that it would have been discovered by operation, even if the patient s condition had permitted one to be performed.

As surgeons we are of course entirely dependent on physicians for the opportunity of operating on cases of perforation in typhoid fever and it is evident that it is for us to convince them that operations may save life. The case which I have recorded is one in which the saving of life was primarily due to Dr Norman Moore and in recording it I do not wish to suggest that all cases are likely to be so successful On the other hand I do think that in the present position of intestinal surgery there is good reason to advocate that the chance given by operation should not be withheld in any case of perforation and I would suggest that in all such cases where perforation is suspected a surgeon should be called in as promptly as possible.

Manchester-square W

WESTON-SUPER-MARE ISOLATION HOSPITAL.—On Dec 17th an additional ward which has been recently added to the Weston super Mare Isolation Hospital was formally opened by the chairman of the sanitary committee The new ward will provide accommodation for eight patients and has been erected at a cost of £300 The hospital now contains 28 beds rise to cow pox, this being further communicated to other milkers who were thereby rendered immune to small pox. The lesions occasioned by grease in man have sufficient resemblance to the cow pox to make one think of the possibility of such an infection especially in grooms, farriers, horse-keepers, and so forth Bosc and Bourquier[42] have recorded the case of a woman who according to them accidentally contracted sheep-pox (variolæ ovinæ) and developed variola like lesions about the hands and forearms

---

[1] A paper read at a meeting of the Clinical Society of London on Dec. 12th 1902.

8 As to the influence of intercurrent diseases on vaccination and *vice versâ* Jenner[43] mentions the case of a boy who the day preceding the insertion of the cow pox had sickened with the measles Both diseases went through their usual phases uninfluenced the one by the other except that the vaccine vesicles enlarged without any surrounding efflorescence, which appeared later, having suffered a temporary suspension on account of the measles Jenner[44] had also noticed that papular eruptions which had long been troublesome were speedily swept away as a result of vaccination A similar effect is noted by Dr Radcliffe Crocker[45] as regards eczema which may sometimes be cured by vaccination, he further observes that eczematous children, otherwise in good health, may often be vaccinated without any aggravation of the eczema. This is a point of some practical importance Where there is danger from small pox, vaccination should be done in such cases on sound skin, the inoculated areas being carefully protected to avoid a transference of inoculable material to other parts of the child s body

Jenner saw scarlet fever develop on the eighth day after vaccination, but the only deviation in the respective evolution of the two conditions was just the same as in the case of measles which I have already mentioned—viz, the areola round the vaccine vesicle was delayed, but it appeared as soon as the patient got better of the scarlet fever It was otherwise, however, with the patient's sister Her scarlet fever rash and symptoms were interrupted in their development and were delayed until the vaccine vesicle began to subside and to dry up, when her throat became sore and the scarlet fever rash spread all over her[46] On the other hand, Dr Radcliffe Crocker[47] mentions a case in which the child was unwittingly vaccinated during the incubation of scarlet fever, which developed before the eighth day of vaccination. All four vaccination areas coalesced into a slough of the size of a crown piece, the child recovered. Trousseau[48] found that measles and scarlet fever arrested the vaccinia in its development, the latter resuming its course when the acute exanthem had subsided. The French observer further noted that variola and vaccinia developed simultaneously without influencing one another whereas other observers contended that variola was favourably influenced by vaccination performed during the incubation period of the former The fact is that it is the right thing to vaccinate as quickly as possible any unprotected individual who has been exposed to small pox.

As to syphilis, I have not seen any complications of either the syphilis or the vaccination in the later stages of a secondary syphilide Balzer[49] however, has recorded confluent sloughing of the vaccinated areas Such a complication might depend on various factors And it would be interesting to know if vaccination is influenced by chronic poisoning by alcohol, lead, and so forth, or by drugs If any readers know of any such facts I shall be glad of information on the point Trousseau[50] remarks that congenital syphilis either in the latent or florid state does not influence vaccination

Dr E W Goodall and Dr C Basan[51] record hæmorrhage into and around the vaccine vesicles in a girl, 11 years of age, who had been vaccinated a few days before an attack of diphtheria. She exhibited at the same time purpuric lesions about the extremities and on the trunk with bleeding from the nose and mouth About 11 days before the purpura she had been injected with 6000 units of antitoxin, this was followed by some urticaria which rapidly disappeared Dr Goodall and Dr Basan exclude the antitoxin as the cause of the hæmorrhages and rightly, I think, attribute it to the diphtheria poison itself Trousseau[52] long ago pointed out that petechiæ epistaxis, and ecchymoses occurred in diphtheria I have not seen vaccination influence an existing widespread psoriasis one way or the other, but psoriasis papules may appear on recently or old vaccinated areas occasionally Nor have I seen bad effects from vaccination in obstinate urticaria, although *a priori* one would expect an aggravation of the latter condition.

9 These considerations lead me to vaccination as a mode of treatment. It is well known that nævi can sometimes be cured by vaccinating upon them Care must be taken to scarify such very lightly Jasiewicz has gone extensively into the prophylactic and curative action of vaccinia as regards a variety of infectious diseases[53] This aspect of the matter has been dealt with to some extent in my previous remarks. But here Jasiewicz recommends the vaccine virus as a therapeutic agent on the principle that one toxin may neutralise or counteract another It may be pointed out, however, that by adding its own effects to those of the toxin already present in the body it may make matters worse. That one disease may influence another beneficially is illustrated by what has been observed with regard to erysipelas a spontaneous attack of which on the face, for instance, may act favourably on a lupus vulgaris This is the idea underlying the use of Coley's fluid

It would appear that vaccination has benefited whooping cough, a fact which Delobel and Cozette state was known to Jenner, but I have not come across the point in the papers of Jenner I have perused[54] Indeed, the French writers whom I have just mentioned say that they have personally observed whooping cough to be cured by vaccination[55] Influenza and pneumonia have also been improved, it is said It has been observed by Beaven Rake that leprosy was arrested in its development by vaccination[56] Of course, in leprosy it is sometimes difficult to tell what is due to treatment, as spontaneous involution of lesions may occur and amelioration may take place for a time without any active treatment at all As to phthisis, Tyndal has seen the febrile and other symptoms improve after several subcutaneous injections of two drops of calf lymph in 15 drops of distilled water and one gramme of glycerine[57] Winogradoff, having noticed that an intercurrent attack of variola improved pulmonary tuberculosis, is said to have also obtained good results from systematic subcutaneous injections of calf lymph in that disease.[58]

This concludes my survey of a subject of great interest. I have only taken a bird's eye view of it, for exhaustively dealt with it might be almost indefinitely expanded, the literature connected with it being enormous. It now remains for me to summarise. The upshot of my remarks is the necessity for scrupulous cleanliness. The operation is a trivial one but any interference with the continuity of the skin, however small, opens the door to infection. We can always learn something from opponents and rivals—that is, if we are not above being taught. The criticism of those who are against vaccination has directed attention to the necessity of all round cleanliness in vaccination. The next point of importance is the calf lymph It should be carefully prepared on the lines which experimental investigation has proved to be the right ones, absolute cleanliness being an essential feature. After the operation the vaccinated areas should be properly protected from the patient's nails and so forth In this way preventable rashes and complications will be prevented On the other hand there are certain factors which are not under our control, such as idiosyncrasy, renal inadequacy cardiac insufficiency, and so forth, but the eruptions which arise in these cases are usually of an evanescent and trivial nature When several patients are vaccinated at the same time with the same lymph these individual factors are brought out one patient will have a rash, the others exhibiting nothing of the kind.

The employment of the "*lancettes plumes*" on a metallic

[58] Op cit (note 53) p 120

Let us now consider what these facts disclose concerning the diffusibility of the scarlet fever virus First let us take the 48 families wherein successful home isolation was conducted The patients were all children of working men. The houses consisted of a room, kitchen, and scullery on the ground floor with three bedrooms upstairs In each house a room was prepared for the patient, generally upstairs , occasionally, however, the front room on the ground floor was cleared for his reception This latter it may be stated, is separated from the kitchen or living room by a short passage about four feet square and one or two doors. Here, then, is a scarlet fever case inhabiting during the whole course of his illness and convalescence one of the apartments of a house (of dimensions described above) while throughout the whole of the same period susceptible children occupy with impunity the other rooms of the same dwelling Again let it be noted that in all those households the mother was necessarily obliged to act the double part of nurse and housewife. During those six or seven weeks she had to nurse, to feed, to wash and to attend to all the wants and requirements of the sick child and meanwhile she was at the same time cook, washerwoman, and general handmaid to the healthy members of the household Once more, during all those weeks she is passing to and fro between the infected and *non infected* apartments as frequently and freely as her multifarious and combined duties demand In each and all of those 48 houses this went on with perfect safety , there were susceptible children in every one of those houses. Nevertheless, throughout all those weeks, although there were daily and even hourly opportunities presented for the conveyance of infection through the medium of the mother, *no transmission* occurred.

As already mentioned, in each of the 34 houses of Division III , contact admittedly in each instance first took place a day or two before the occurrence of the second case—an admission strikingly confirmed by the great differences seen in the length of the intervals separating the occurrences in Division III. when compared with those of Division I It is very far from my desire or wish to appear dogmatic in any way, still I think a reasonable inference from the foregoing observations would favour the view that a healthy nurse or attendant on a *scarlet fever case does* not in ordinary circumstances carry the infection of scarlet fever, even from one room *to another*

For several years now I have been earnestly seeking after a genuine instance of a healthy person playing the part of a medium in the transmission of scarlet fever I have tacitly encouraged mothers to visit their neighbours' sick children, knowing full well that in this small community where everybody is pretty well known to me I should very quickly discover if any of the visitors conveyed the disease to their own homes I have seized every opportunity to instigate exposure on these lines in a great many other ways, with so far always the same negative results. For the sake of brevity fomites have not been touched upon , besides the mechanic does not generally carry such encumbrances to his workshop or the factory girl to her mill, and in any case should danger eventually be proved to lurk in fomites some simple regulations could surely be devised to dispose of them and to render them innocuous.

To sum up in this investigation we have had before us, say, Division III. 34 households, and *Division IV 48 households* To put it in other words, we have had under observation 82 different sets of *circumstances*, each, so far as our present knowledge goes, in every way calculated to promote the transmission of infection in the manner specified yet no transmission occurs It may be the weight of the scale containing the virus , it may be the drying or the rapid devitalisation of the virus or it may be some cause or condition as yet unsuspected which prevents the infection being carried by an attendant or nurse even from *one room* to another still the public have a right to demand from the medical profession a positive finding and *definite* pronouncement of the facts herein related and somewhat cursorily discussed.

In conclusion, let me add a case in point recently seen by me—that of a boy, six years of age, suffering from scarlet fever (there is no hospital provision in this district for scarlet fever) The boy is confined strictly to one room , no one enters it but the mother Three of his sisters have to-day been notified by the overlooker of the factory where they are employed that they are "stopped " until their brother is well. Now this means a loss of 30s a week to these poor people. Strange to say, however scarlet fever occurred in this family five years ago, and by conscientiously confining the then patient to her room all the others escaped The mother now resents this enforced loss very much and pertinently asks me why if she did not carry the infection from one room to another five years ago it can be possible now for her daughters to carry the infection to a factory two miles off?

Netherfield.

BENCE-JONES ALBUMOSURIA, WITH REPORT OF THREE CASES

BY JAMES M ANDERS, M.D , PH.D LL D ,

PROFESSOR OF THE PRACTICE OF MEDICINE AND CLINICAL MEDICINE IN THE MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA ATTENDING PHYSICIAN TO THE MEDICO-CHIRURGICAL HOSPITAL, PHILADELPHIA, ETC ,

AND

L. NAPOLEON BOSTON, A.M., M.D ,

BACTERIOLOGIST TO THE PHILADELPHIA HOSPITAL DEMONSTRATOR IN CHARGE OF THE CLINICAL LABORATORY OF THE MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA

ALBUMOSE may appear in the urine as a result of pathological conditions and is dependent upon the decomposition of organised proteids except in cases of the enterogenic form. It may owe its origin to the action of bacteria upon tissues or it may result from the action of certain chemical poisons (phosphorus) It is also observed in connexion with the various cirrhoses of the liver, acute yellow atrophy, gastric cancer, gangrene, acute or chronic suppuration, acute inflammations of the serous surfaces leucocythæmia, the acute infectious fevers, after death of the fœtus and normally during involution of the uterus Rarely has Bence-Jones albumosuria been observed to be a co-existing feature of primary lesions of the bones (*myeloma*), and at least one of the cases reported below exemplifies this form of the condition In 1847 Henry Bence-Jones presented the first recorded instance before the Royal Society of London , and three years later MacIntyre published a clinical report of this case The discovery of Bence-Jones appears to have received but little attention for a period of 24 years when Kühne (Solly reported a questionable case, however in 1846) detected this substance in the urine , but it was not until 1883 that Kühne published a report of his observation in connexion with the clinical history by Stokvis. In 1889 Kahler and Huppert reported a case from a clinical and chemical standpoint respectively , Stokvis recorded a second case in 1891, Seegelken a case in 1895, and Bozzolo in 1897 recorded another under the title of 'Sulla Malattia di Kahler," thus recognising Kahler as the one first to designate the relation existing between albumosuria and primary bone lesions. Von Rustizky as early as 1873, however classified these lesions as ' *multiples myelom.*" Rosin (Senator) Ewald Fitz, Naunyn, Bradshaw, Ellinger J A. Milroy and J H. Wright contributed cases during this year Vladimer de Holstein Sternberg Askanazy, Raschkes, Hamburger Kalischer, Rostoski, Jochmann and Schumm and A. Gutterink and C de Groff have also made valuable contributions to the literature of the subject

Since the original publication of Bence-Jones's discovery of albumosuria associated with "osteomalacia fragilis rubra" there have appeared in the *literature* records of 21 cases in which neoplasm of the bones regarded as probable myelomata was disclosed post mortem In eight cases the tumours were observed ante mortem. In addition to those cases displaying a *co-existence* of albumosuria and primary myelomata von Jaksch and Fitz have each found albumosuria in a case of myxœdema and Askanazy noted it to be a prominent feature in one of lymphatic leukemia, while Zuelzer observed this body present in the urine of a dog poisoned by pyrodin. To the above cases 30 in all, should be added three of albumosuria that occurred in our own experience and are herewith reported.

CASE 1.—A man, aged 32 years first came under the care of one of us (Boston) The patient was exceptionally well developed and was fond of athletics He was born in California and had had the diseases of childhood, including scarlet fever at the age of 14 years, after which period he

A NEW DIFFERENTIAL STAIN FOR THE KLEBS-LÖFFLER BACILLUS OF DIPHTHERIA

BY J WICLIFFE PECK, F C S

AFTER using the method suggested by Neisser for staining the Klebs Löffler bacillus for some years, bacteriologists have to agree that it has a very limited use indeed In the examination of direct swabbings it is reliable in 60 per cent. of the cases only and if the culture on blood serum or Kanthack s serum agar is more than 24 hours old it is not reliable.

After making a number of experiments to find, if possible, a stain that will be of more extended use I have found one that partly satisfies the need The stain which I have used is Löffler s methylene blue and as a counter stain Neisser s brown The film is spread in the usual way, fixed in the flame, stained with Löffler s methylene blue for from three to four seconds washed quickly, then counter stained with Vesuvian 0 2 per cent aqueous solution for 30 seconds, again washed quickly, dried, and mounted in Canada balsam The film may be dried on the slide and stained without the use of a cover slip It is convenient to have two very wide mouthed, stoppered bottles of the stains, and the films simply dipped in for the proper time This method gives a better result in all instances in which Neisser's acetic acid stain has been used, and it has this great advantage that it is reliable for staining the Klebs Löffler bacillus from a culture on blood serum several days old I kept one culture at 35 5° C during a week and another at 20° C after incubating at 35 5° C for 24 hours, and while the former was very much involuted after five days the other was not so much so after eight days And I found that the new method, which might be called the ' Löffler Neisser method," was quite reliable for staining the former up to four days, while a good differential staining was obtained with the latter on the eighth day

For staining direct swabbings the Löffler Neisser stain is quite reliable In every instance which I tried of swabbings several days old I found the new method stained them well, while Neisser's method stained them very indistinctly or only indistinctly stained two or three organisms A dry four days' old swabbing was moistened with broth and two cover slip specimens were made. One, stained by the Löffler Neisser method, showed a large number of the Klebs Löffler bacilli clearly defined The other, stained by Neisser's method (30 seconds each) showed only three organisms resembling the Klebs Löffler bacillus and these were indistinct On cultivation the Klebs Löffler bacilli were in almost pure culture This stain is always ready at hand and is a very rapid method It is also interesting in being an alkaline stain, while Neisser's is very strongly acid The common mouth organisms do not stain in the three seconds that are required, and neither the bacillus of Hofman nor bacillus coryzæ segmentosus stain by this method The bacillus pseudo-diphtheriæ which is non pathogenic, occasionally stains by Neisser's and the Löffler Neisser methods, but after a number of attempts I only once succeeded in staining the (20 hours' old) organism by these methods. After three days I could not get it to stain by either method The very luxurious growth, fine orange yellow colour, and morphological appearance with ordinary blue staining preclude the possibility of mistaking this organism. Löffler s blood serum gives better results than serum agar and, contrary to what I expected, the Klebs-Löffler bacillus in pure culture grows better on a seven weeks' old blood serum than on one 10 days old, while the difference in the staining properties is not worth considering Agar being an unfavourable medium and producing involution forms so quickly is unsuitable for cultivating the Klebs Löffler bacillus and films from this medium refuse to be stained by either method One pure culture in milk two days old and another four days old stained well with the Löffler Neisser method but gave a negative result with that of Neisser The organisms are found to be clumped together in small masses so that in milk examination the diagnosis would be difficult.

The results mentioned above are the outcome of very numerous experiments with a large number of cultivations from throats and swabbings

I have to express my indebtedness to Dr F A. Bainbridge, of the Hospital for Sick Children Great Ormond-street, and of St. Bartholomew's Hospital for giving me many of the cultures I have used and for his kind advice.

Hospital for Sick Children Great Ormond-street W C

THE DIFFUSIBILITY OF SCARLET FEVER VIRUS

BY JOHN SUTHERLAND, M B , C M , B Sc EDIN.

IN conducting an inquiry lately in an epidemic of scarlet fever directed mainly towards the question of home isolation several noteworthy features relating to the natural history of that disease were disclosed, among which one in particular struck me as important and which, so far as I am aware, has not hitherto been remarked upon—that is, the wonderfully low diffusibility of the scarlet fever virus In the literature of scarlet fever it is generally assumed that this exanthem is carried and propagated by various media—e.g , fomites, visitors, &c —and illustrative examples are given wherein healthy persons coming from a scarlet fever case or from an infected dwelling are said to have carried the infection and communicated the disease to other persons living many miles distant from the supposed source. This means, in other words, that particles containing the virus in some way or other adhered to those persons or to their apparel and retained vitality until such time as the virus got implanted in the new victim The virus cannot certainly retain its vitality indefinitely or very few houses in England would be free from it. Scarlet fever is intensely contagious, and throughout the whole course of the epidemic I have seen only one instance of a susceptible child escaping this disease after contact with a desquamating case. The diffusibility, to some extent, at any rate, must depend on how long the virus can survive and retain its "striking" power after its dissociation from a desquamating subject exposed at the same time to ordinary conditions, meteorological and otherwise If it be true that healthy persons can convey the infection in the way described, then we must assume that either the virus has a separate existence or that it in the form of spores or otherwise remains effective for an as yet unknown period after dissociation from its host.

Again, the question of whether healthy persons do actually carry the infection from one to another is very important in another way, for founded on the assumption that such is the case are many restrictions on labour which bear hardly on the poorer classes In this inquiry 224 cases of scarlet fever occurring in 132 households came under review and the following is a short summary of the result. The plan of isolation consisted mainly in confining the patient to a room until such time as he or she was released by order of the medical attendant and success or failure depended on whether the other susceptible children of the house escaped or not. ' Susceptible children" means those unprotected by a previous attack of scarlet fever

Division I—Ten families either could not or would not keep the infected children apart from the others, so second cases occurred in every one of these homes after intervals of 2, 3, 6 7 8, 9 11, 12, and 14 days respectively, reckoning from the dates on which each of the first cases was seen professionally

Division II—In 40 households the patients were either the only children of the house or the only susceptible ones This group, therefore, affords us no data either one way or another

Division III—In 34 families a very well intentioned attempt at isolation was begun and maintained for periods ranging between 21 and 43 days The respective intervals in this division between the first and second cases were 40, 43, 34, 36, 33, 30, 31, 27, 29, 24, 23, 19, &c , days Now in each of those 34 families a dereliction of duty was admitted. The second case had been in contact with the isolated child two days before he sickened Sometimes the children got together by stealth others came in contact through the connivance of their parents, but the result was invariably the same—a fresh victim in two days

Division IV—In 48 families this home isolation proved pre eminently successful Susceptible children lived in each of these 48 houses and they all escaped

Ophthalmoscopic examination made by L. Webster Fox showed colloid deposits above and below the optic nerve and retinal hæmorrhages in both eyes There was no evidence of optic neuritis, but there was considerable arterio-sclerosis

On Jan. 7th 1902 the patient returned to his home in the country and his physician there reports that on account of racking acute pains in the inferior extremities he was unable to leave his bed. Exertion seemed particularly painful. About one month ago this patient died. No necropsy was permitted.

CASE 3.—A man, aged 33 years of German descent though an American by birth, first came under the care of one of us (Anders) on Oct 12th, 1900 The patient's habits as to the use of intoxicants had been rather intemperate up to a few years ago since which time, however, no stimulants of any description had been used The following significant family history was obtained the mother died from cirrhosis of the liver eight months ago , the father was living at 66 years of age and was afflicted with double cataract , he also suffered from gout and rheumatism. One paternal uncle died from Bright's disease The patient had had the diseases of childhood and from the seventh year of age had annually suffered from an attack of tonsillitis When 18 years old he had diphtheria, followed by facial paralysis of the left side , this complication was ascribed to the application of caustic to the throat. Complete recovery did not ensue and there is still noted an occasional twitching of the muscles, with a tendency to contracture of the facial muscles of the affected side. An ophthalmoscopic examination made by L Webster Fox gave this result "The right eye shows colloid degeneration of the retina as well as sclerosis of the blood vessels. The white deposits so characteristic of chronic interstitial nephritis are defined above and around the macular region. The macula itself has escaped its destructive influences, which accounts for his good vision There is a suspicion of hæmorrhage here and there throughout these deposits. The optic nerve shows slight infiltration , this may be problematic. The left eye shows a normal fundus. There are no deposits and no destruction of the retina The arterio-sclerosis of the blood-vessels is not so pronounced as in the right eye. This is rather peculiar as the blood vessels of both eyes should present the same characteristics The pupillary reaction is normal and the muscles are perfectly balanced '

The present illness was discovered six years ago during an application for life insurance, when albumin and tube casts were discovered in the urine No other subjective or objective signs of kidney disease, however put in an appearance until three years since, when he first observed some malleolar œdema This symptom had recurred at long intervals and he had also suffered from occasional headaches during the same period The physical signs at the time of his first visit showed moderate enlargement of the left ventricle with distinct accentuation of the aortic second sound and slight œdema of the legs The body surface looked pale. These signs have not undergone any noteworthy changes up to the present The urine contained Bence-Jones albumose and other morphological elements to which detailed reference is made below Examination of the blood showed that the hæmoglobin amounted to 69 per cent the red cells numbered 3 200 000 and the white cells 40 000 per cubic millimetre. A differential count gave polynuclear cells 65 per cent , large mononuclear 5 per cent , transitional 4 per cent large lymphocytes 15 per cent small lymphocytes 10 per cent. and eosinophiles 1 per cent , there were no nucleated red cells Poikilocytosis was marked Apart from some emaciation that has occurred during the last six months there has been no appreciable change in the general condition of the patient until the present.

THE URINE

CASE 1 —The urine was of a light straw colour and displayed a persistent froth on shaking , the 24 hours' product equalled 2900 cubic centimetres having the consistence of syrup and was faintly acid except for an occasional specimen which was neutral in its reaction , the specific gravity varied from 1002 to 1010 The quantity of urea was practically normal and the urine was found to be free from sugar The total amount of proteid by the Esbach method equalled 0 27 to 0 35 per cent. It was precipitated by nitric, sulphuric, and hydrochloric acids, but was not soluble in excess except by the aid of heat. 13 other reagents employed for the detection of serum albumin gave decided reaction for that body [1] Casts were not found at any time. The tests employed have been those suggested by Huppert, Mathes, and Milroy

1 More striking were the changes observed upon the gentle application of heat to the filtered urine. When heated on a water bath it showed a slight turbidity at about 50° C and at from 56° to 60° it became opaque and a white precipitate in the form of coarse flocculi was observed, which for the most part was redissolved at a temperature of from 90° to 95° C A test-tube filled to two-thirds of its depth was placed over the flame of a Bunsen burner so as to heat only the upper third of the column of urine. As the temperature reached from 52° to 54° C an opalescence was observed which developed into a dense cloud at from 56° to 60° C and formed a rather heavy coagulum when heated to a temperature between 60° and 90° C The addition of a few drops of dilute acetic acid to the urine caused the opalescence to appear at a lower temperature (37° C) In case the heating was continued at a temperature of from 95° to 100° C this coagulum would disappear (dissolve) in part and often entirely when ebullition was prolonged for one minute, but when allowed to cool the urine became equally as turbid as it was before the boiling temperature had been reached, or even more turbid

2. Upon the addition of concentrated nitric acid drop by drop to the urine after heating the upper third of the column it caused a precipitate to appear in the track of the acid as it traversed the cold stratum of the urine to the bottom where after the addition of several drops, a rather dense precipitate of a pink or yellowish hue was seen which on standing developed a golden colour

3 Nitric acid added drop by drop, shaking after each additional drop, caused a slight pinkish colour, affecting most the heated portion of the column

4 A specimen of the acidulated urine was gradually heated to the boiling point, cooled and filtered and the filtrate thus obtained apparently contained but little proteid displaying a slight opalescence with acetic acid but no precipitate resulted when nitric acid was employed. The latter caused a pink tint to appear which became yellowish on the addition of ammonia.

5 A quantity of the urine was placed in a beaker and heated to from 52° to 54° C., cooled and filtered The precipitate collected was dissolved by washing with a solution of soda of a specific gravity of 116 When thus prepared it gave well marked Millon's and biuret reactions The precipitate, when heated with lead acetate and caustic soda (30 per cent) became blackened due to the formation of lead sulphide, showing that the precipitate obtained in this manner contains sulphur in considerable amount. Boiling before filtering altered in no way these reactions

SATURATION WITH NEUTRAL SALTS.

CASE I.—A quantity of urine was saturated with a neutral solution of ammonium sulphate which completely precipitated the albumose. Saturation with sodium chloride in neutral solution caused a precipitate of but a portion of the albumose the filtrate giving a decided clouding upon the addition of a small quantity of dilute acetic acid , but the filtrate from the second precipitate did not contain albumose. The body with which we are dealing differs from proto- and hetero albumose in that it is not completely precipitated with sodium chloride in neutral solution. It resembles hetero-albumose in that it is precipitated on the addition of acetic acid, after saturation with sodium chloride, or magnesium sulphate, but differs from this body in being precipitated at a temperature of 52° C A test-tube containing urine saturated with neutral sodium chloride solution to which a few drops of nitric acid were added gave a precipitate on heating, which disappeared on nearing the boiling point but reappeared upon cooling Saturation with neutral salt exercised but little effect upon the precipitate caused by sulphuric and hydrochloric acids It was also precipitated by tannic and picric acids After acidulating the urine with dilute acetic acid and heating sufficiently to precipitate the albumose the temperature was raised sufficiently to dissolve it and upon the addition of a few drops of nitric acid the precipitate did not reappear with the usual rapidity upon cooling Urine saturated with neutral salt to which a few drops of nitric acid were added and the temperature rapidly brought to the boiling point showed but little tendency to form a precipitate upon enjoyed perfect health except for an attack of malaria at 20 years of age which was followed by several relapses continuing over a period of more than a year His father died from Bright's disease at 56 years of age and his mother from apoplexy at 55 years of age, both were large in stature weighing over 200 pounds A brother and a sister died during childhood (cause unknown)

---

[1] Boston: New York Medical Journal 1902 (Albumin in the Urine A New Way for applying Nitric Acid and other Reagents)

The following is the history of the patient's last illness On Sept 20th 1900, while working at his trade he fell from the second storey of a building to the cellar, a distance of 20 feet. He was found unconscious by his fellow workmen and was taken to the hospital, where he soon recovered consciousness and was allowed to walk to his home As a result of this fall he complained of soreness in his back confined to the lower dorsal and lumbar regions, but he returned to his work a week later During the latter part of November, 1900, he developed a typical form of herpes zoster affecting the right side. At this time he was voiding 1900 cubic centimetres of a pale urine during the 24 hours He first noticed intense thirst which was allayed only by drinking large quantities of water During December he complained of weakness, dimness of vision which caused him to remain from work for a time, and pronounced frontal headaches Early in January 1901 he returned to work, when on lifting a piece of timber he was seized with severe pain in the lumbar region accompanied by a feeling of "giving away of the backbone" as he expressed it, and was carried to his home. At this time tenderness could be elicited by deep pressure over the lower dorsal vertebræ and this was also present though less marked, over the lumbar vertebræ and crest of the right ilium There was more or less constant pain in these regions and in the right thigh Two weeks later he experienced a similar 'giving away' in the right hip while ascending the stairs Repeated subsequent attacks of this nature affecting either the hip or back, were experienced In February the patient stated that he had lost 60 pounds in weight during the previous 12 weeks, he now weighed 135 pounds. There were a decided pallor and a peculiar expression the eyes having a staring prominence with œdema beneath them which at times involved the entire face and greatly distorted the features Œdema of the hands and feet was present, that of the latter increasing as the disease advanced

On March 10th the patient was seized with intense pain over the region of the liver which followed an attack of vomiting There was now present a small nodule apparently developing from the eighth rib in the mid axillary line, this soon grew to the size of a horse chestnut. Both the patient and the nurse insisted that this lump enlarged during each paroxysm of vomiting, and that firm pressure over the tumour diminished its size and gave the patient almost instant relief from pain At about this time he complained of pain (cramp-like) in the right thigh and of extreme tenderness on the inner surface of the femur at the junction of its upper and middle thirds On April 22nd (the date of death) this region displayed a tumour of the size of a hen's egg, developing from the femur Neither crepitus (a symptom to which other observers have called attention) nor fluctuation was present. A tumour had also protruded from the posterior border of the right tonsil which interfered with deglutition and prevented the use of solid foods This mass was also painful but the mucous surface of the throat presented nothing abnormal.

The area of cardiac dulness was slightly increased downwards and to the left. A soft systolic murmur was audible at the apex and was transmitted for a distance of three inches towards the axilla There was also a soft systolic murmur heard over the base of the heart (hæmic) and faintly transmitted to the carotids The pulse ranged from 75 to 120 beats per minute but was slow in proportion to the degree of prostration Later it became compressible and intermittent. There was no atheroma of the arteries Epistaxis was copious and frequent Vomiting both before and after the taking of food was an early feature and persisted throughout. Constipation developed early Cephalalgia was constantly present in the frontal region but occasionally became parietal and occipital. Upon firm pressure an extremely tender area was detected over the left orbit The hearing was dulled and tinnitus was annoying Insomnia became marked about Jan 1st, after which he was unable to sleep soundly without the aid of drugs Cramps in the lower limbs, at times limited to the thighs caused great suffering The voice was husky and the speech was slow and somewhat "drawn." In addition to the decided loss of sight before mentioned and the constant floating of specks before the eyes an ophthalmoscopic examination by L Webster Fox disclosed choked disc, retinal hæmorrhages, and the white deposits common to chronic nephritis Marked pain on voiding urine which continued throughout the act, was a late symptom The hæmoglobin was found to fluctuate between 52 and 70 per cent, the red cells varied from 3 500 000 to 4 100 000 and the white cells from 8000 to 16 000 per cubic millimetre The red cells reacted normally to stains but poikilocytosis was well marked In the stained specimens the white cells showed nothing abnormal. The urine contained Bence-Jones albumose (*vide infra*). No necropsy was permitted.

CASE 2.—A man, aged 43 years married and temperate as to eating and drinking came under the care of one of us (Anders) on Nov 18th, 1901 The family history revealed gout, rheumatism, and intense headaches among his ancestors The patient had had the diseases of childhood, including three attacks of measles, he had also been troubled with neuralgia during adolescence Three years ago he met with a bicycle accident which resulted in a fracture of the right leg, and although recovery ensued he had since then complained of pains in the seat of fracture. One year ago acute articular rheumatism developed and lasted for three weeks For a considerable period of time he had suffered at intervals from severe celphalalgia affecting the left side of the head In January, 1901, he first discovered certain urinary phenomena which were interpreted by his former physician as belonging to nephritis, he became dyspnœic and at times suffered from cardiac palpitation. The rheumatoid pains had recurred at brief intervals There had been no febrile movement observed, but there had been a rapid reduction of the body weight during the past four months, his usual weight in health was 219 pounds while when first seen it was 167 pounds Hand in hand with the rapid loss of weight the strength had also declined and the patient often alluded to a sudden "giving way' of one or other leg while attempting to walk There had been four severe attacks of epistaxis since March 1901 The speech was thick blurred and slow, the tone was dry and leathery' resembling the voice in myxœdema. The patient often complained of intensely painful shins, especially when they were warmed by the bed clothes Occasional pains affecting the lower extremities and wandering pains about the arms shoulders and back were complained of, and insomnia had been a troublesome feature during the past three months, although he slept well for a single night at intervals of several days Violent headaches in the form of hemicrania affecting the left side had been present for a period of about four months, this symptom was remittent and occasionally intermittent but it was exceedingly severe at some portion of each day, particularly during the early morning hours and demanded anodynes for its relief Pressure above the left orbit showed a painful tender spot corresponding with the point of emergence of the supraorbital nerve The sexual function had been in abeyance for a considerable period of time The appetite was poor and the liver function was decidedly sluggish In order to regulate the bowels the patient had been obliged to use a laxative daily Vomiting occurred at irregular intervals, at times on rising in the morning, and again though less commonly after food Walking early induced fatigue The temperature was slightly subnormal as a rule

The left ventricle was slightly hypertrophied and the aortic second sound was perhaps slightly accentuated, but the pulse was weak soft, and compressible. No murmurs were audible over the præcordium The eyes bulged and the gaze was staring, the skin presented a dirty yellow or sallow colour, the facies expressed suffering as a rule No tumour masses were detected, although the skull sternum, and shins were tender to pressure The urine contained Bence-Jones albumose a symptom to which allusion will be made later Examination of the blood showed that the red cells numbered 3 750 000 and the white cells 23,000 per cubic millimetre, the hæmoglobin amounting to 60 per cent. Poikilocytosis was marked and the red cells reacted normally to stains The differential count gave polymorphonuclear 72 12 per cent, large lymphocytes 8 17 per cent small lymphocytes 11 06 per cent., transitional 2 9 per cent, and large mononuclear 5 8 per cent. No nucleated red or eosinophilic cells were found 200 white cells were counted he bony skeleton. At times it is dull and constant, again cramp-like, lancinating and momentary Pressure over painful bones intensifies it, as does also exercise. While the pains are commonest over the flat bones the extremities often share this agonising symptom. Cramps involving the lower extremities are common. Toothache, loosening of teeth, maxillary necrosis, and salivation may develop Painful deglutition developed late in Case 1 of our series Facial neuralgia is mentioned in connexion with 30 per cent. of the cases Paralysis of the hypoglossal nerves and of the third division of the trifacial nerve is reported One of our cases (No 3) showed paralysis and twitching of the left side of the face. Cephalalgia is mentioned as a prominent symptom in 70 per cent. of the cases. In Cases 1 and 2 of our series it was most troublesome and in Case 3 it developed periodically Hand in hand with rapid and progressive emaciation are noticed pallor, anæmia, prostration, and gastro-intestinal symptoms as nausea, vomiting diarrhœa, and constipation In one instance jaundice developed early

Deformities—In 67 per cent of all cases deformities involving the bones of either the thorax, pelvis, spine, cranium, maxilla, or extremities were apparent during life. Pathological fractures occurring without apparent cause are a common complication and were observed in one-fourth of all cases Glandular enlargement is recorded in connexion with 15 per cent. of the cases but in none of these did microscopic study show the growths of the glands to be identical with those developing from the bones

Frequent painful micturition was a late symptom in one of our cases The urine is said to have been passed frequently in four other cases Epistaxis proved an early and annoying symptom in two of our cases and was occasionally present in the third. Changes in the voice are recorded in 16⅔ per cent. of the cases while in 12½ per cent. impairment of the auditory function existed. Tachycardia palpitation and dyspnœa are repeatedly referred to in the literature and were prominent in our cases. Insomnia was present in three of the cases furnished by the literature and in two of our series (25 per cent. of the cases) A moderate degree of pallor has been a constant feature. The skin is dry and harsh and at times presents a muddy or dirty yellow colour

Mention is made of impairment of vision in four cases furnished by the literature One developed glaucoma and another showed strabismus and double vision. In our cases failing sight was an early and progressive symptom. Ophthalmoscopic examination revealed sclerosis of the vessels, colloid degeneration of the retina, retinal hæmorrhages and the white deposits common to chronic nephritis Reference is made to a rather severe progressive anæmia in most of the cases for example, in those of Ellinger, Askanazy Vickery Musser and Fitz whilst in our series it was more moderate Record of a complete blood examination appears in connexion with but eight cases, including the three herein reported. Our cases showed leucocytosis of 16 000 23 000 and 40 000 per cubic millimetre respectively red cells between 3 200 000 and 3 750 000 and hæmoglobin between 60 and 70 per cent. Eosinophilic cells were diminished in one and absent in two Pneumonia as a complication is given as a cause of death in 12½ per cent of the cases The duration of the condition is usually less than two years, one case, however is recorded in which albumosuria persisted for more than eight years

Bence Jones albumose is a body more or less closely allied to peptones globin histon, and the digestive albumoses but it displays certain characteristics unknown to these substances. It is a normal constituent of spermatic fluid and may be found in the bone marrow in cases of myeloma. In conclusion Bence-Jones albumose when present in the urine is invaluable as a diagnostic feature in cases of obscure multiple myeloma in which no other symptoms of this disease exist. It also serves in differentiating multiple myeloma from other bone lesions as carcinoma, sarcoma, osteomalacia, &c Albumosuria if continuous is of grave prognostic significance and but a single exception is recorded wherein the disease has not proved fatal in less than two years Where the albumose has persisted for some time its disappearance signifies approaching danger and probably an early fatal issue. Since serum albumin is a common co-existent of Bence-Jones albumose its disappearance from such urine may also presage complications of a serious character

Philadelphia.

AN AMERICAN PATENT —An American inventor has patented a combined lid or cover and canopy for coffins and caskets The specification and drawing are given in the *Official Gazette* of the United States Patent Office issued on Dec 16th The illustration shows a hinged or jointed framework attached to the upper edge of a coffin, by means of which framework the lid may be supported at a height above the coffin approximately equal to the depth of the coffin itself The purpose thereby intended to be served is not stated.

cooling At times this precipitate did not appear for one or more hours The method commonly employed in these analyses was to saturate the urine with a solution of neutral salt, then a drop or two of dilute acetic acid were added, and the temperature was gradually raised to the boiling point, the urine was filtered hot, and the collected coagulum was then readily dissolved by washing with a solution of soda of a specific gravity of 116, after which it was tested for Millon's, the biuret, and sulphur reactions The filtrate thus obtained contained albumose, contrary to what one would ordinarily expect. From 30 to 50 cubic centimetres were placed in a beaker and a drop of hydrochloric acid was added stirring gently, when a few drops of phosphotungstic acid were added and heat was gently applied which when prolonged for a few minutes caused a copious precipitate to collect at the bottom in the form of a rather tough whitish mass. The clear supernatant fluid was decanted and this second precipitate was washed and dissolved in a solution of soda of a specific gravity of 116 adding drop by drop This usually gave a colourless mixture, but occasionally it was noted to possess a blue tint which disappeared when the specimen was gently heated A 1 per cent solution of copper sulphate was now added drop by drop when a purple colour would appear, rapidly *changing to a pink or rich claret. On standing a golden* yellow precipitate collected at the bottom of the tube The second precipitate when dissolved was also treated with Millon's reagent and gave a bright red colour

In Bence-Jones's, Kühne's, and Matthes' cases the proteid contained phosphorus while in Milroy's case not a trace of phosphorus was found. No such studies were conducted in connexion with our cases Neither were Hofmeister's, Noel Paton's or Hopkins and Pinkus's methods employed for the crystallisation of this proteid.

Microscopic study showed the urine to contain few leucocytes, an occasional red blood cell epithelial cells (bladder), and a few bacteria cocci and bacilli which were only present in the neutral specimens No renal casts were found though many specimens were centrifugated and carefully examined Polyuria was present in one of Hamburger's cases in which the patient voided 3500 cubic centimetres daily, while Kahler's patient voided 2230 cubic centimetres In Case 1 of our series the patient passed 2900 cubic centimetres per diem while in Cases 2 and 3 the patients passed 2500 and 2300 cubic centimetres respectively

CASE 2 —The urine was as a rule feebly acid but was occasionally neutral. The 24 hours' product was 2500 cubic centimetres, more recently only 1875 cubic centimetres There was froth in excess, the urine was of a light straw colour and the specific gravity ranged from 1004 to 1012. The standing specimen showed only a slight amount of sediment The total proteid estimated by the Esbach method ranged from 0 233 to 0 0012 per cent Over a period of several months albumose was present at each analysis the tests detailed above having been employed During the last month of life the total amount of proteid was much reduced and a reaction for albumose could not be obtained In this particular it resembles Stokvis's case in which the albumosuria disappeared three months before death The albumosuria, however did not assert itself in his case until late in the course of the disease, and this may have been true of our case since the patient had been ill for a long time and had lost 60 pounds in weight before consulting one of us (Anders) Microscopically the centrifugated specimens contained bladder epithelium, amorphous urates few leucocytes, and an occasional red cell Casts were not found Certain of the specimens contained many bacteria (motile bacilli) and the question as to how this condition might influence the reactions for the Bence-Jones body naturally suggested itself, and further observation showed that the bacteriuria, when present, exercised no influence upon the reactions for albumose

CASE 3 —The urine was usually clear, colourless and acid, the 24 hours' product equalled 2300 cubic centimetres, the specific gravity ranging from 1008 to 1012 The total amount of proteid estimated by the Esbach method varied from 0 01 to 0 03 per cent Serum albumin was always present in large amount Bence Jones albumose which was first found on Oct 25th, 1901 was not a constant constituent until recently, it has been of late noted at each examination. When the urine contained albumose it was always noted to be of the consistence of syrup and when a drop was evaporated nearly to dryness it was found to be markedly viscid. This appears to be the sixth recorded instance in which urine containing albumose resembled syrup In Case 1 of our series it was also observed Microscopically, small hyaline, granular, and large (so-called amyloid) casts were always present, there were few epithelial cells, and leucocytes were occasionally found Casts were present in Bence Jones and MacIntyre's case and mention is made of their having been found in cases cited by Senator, Fitz, Hamburger, and Raschkes

Albumose resembles, in many respects, histon which may under certain conditions be derived from nucleo histon, a proteid of the leucocytes According to Milroy, histon resembles more closely globin than albumose and seems to be intermediate in its properties between acid albumin and albumose. Histon is precipitated from acid solutions by ammonia, while in albumose no precipitate occurs Lilienfeld found that this body (histon) yielded a precipitate when heated, which was soluble in dilute acids It was precipitated on the addition of nitric acid, this precipitate disappeared on heating to reappear on cooling It gave a distinct rose-pink colour with copper sulphate and caustic soda Huppert first observed the resemblance existing between albumose as found in Bence-Jones albumosuria and the proteid constituent of hæmoglobin. Schultz has also studied these bodies and his conclusions are essentially the same as those of Milroy "*The two bodies resemble one another in their* behaviour on the addition of hydrochloric and nitric acids and also in the fact that they both give the biuret reaction. The albumose differs from globin in being less easily precipitated by the addition of neutral salts, in giving a distinct reaction with Millon's reagent and in containing loosely combined sulphur" When precipitated by heat globin is readily soluble in dilute acids, a feature less marked in albumose

A review of the cases of albumosuria available in the literature 30 in number, and a more careful study of our own three examples reported above, making a total of 3 cases appear to warrant the following inferences

Etiology —Albumosuria is a condition which manifests itself after the age of 30 years Of our series one occurred at 32 another at 33 and a third at 36 years of age. Of the cases found in the literature one developed at 24, another at 37, 10 between 40 and 50 one between 50 and 60 and seven between 60 and 70 years of age In the remaining cases the age could not be ascertained Males are affected in 80 per cent. of the cases In 15 per cent. of the cases (including two of our own) there is a history of an accident inflicting rather severe traumatism Primary lesions of the bones which should be regarded as multiple myeloma figured in 80 per cent of the cases Of these the bones of the chest, vertebræ and pelvis suffered most destruction while one fourth likewise presented involvement of the long bones—femur, radius, and humerus An extreme grade o anæmia has been regarded by many writers as a predisposing factor, while others consider the anæmia to be secondary t myeloma. According to the blood findings in our own cases the latter view is probably the correct one. Experimentally albumosuria results from the administration of pyrodin.

Symptomatology —Albumosuria may be persistent, transitory, or less commonly remittent occurring in variabl degrees at different hours during the day In certain of the cases the urine presented this phenomenon (albumosuria after the disease was well advanced while in others it disappeared when the disease was at its height. Where the urine contained both serum albumin and albumose the former has been noted to be absent a few days before death In but two instances was the percentage of albumose estimated. The specific gravity ranged from 1040 to 1004 In six cases, including two of our own (Nos 1 and 3) the urine resembled syrup Polyuria is mentioned b Kahler, Kalischer and Hamburger and has been prominent feature in our three cases Serum albumin i stated to have been found in conjunction with albumose i 30 per cent of the cases nearly all of which showed eithe hyaline or amyloid casts A small amount of serum albumin was present in two of our cases in the third th percentage was large, while only one of them showed tub casts We are forced to regard albumosuria as a conditio not dependent upon any known pathological changes in th kidneys themselves, but one that may appear in connexio with renal lesions Pain is an almost constant feature, single exception existing It is usually referred to a bone pains rheumatism lumbago, neuralgia, &c. Th pain occurs without apparent cause, is severe, and is ofte accompanied by a 'giving away" of some portion o ength some irritation of the nasal mucous membrane nerally occurred, as evidenced by the animal standing up its hind legs and rubbing its nose with the fore paws for me little time. A 2 per cent. solution generally led to lema of the ears after a few days. One cubic centimetre a 1 per cent. solution injected about every other day presenting a proportion of about 0 00045 gramme per 100 ammes body weight led to progressive emaciation when olonged for more than a fortnight 200 grammes being st in nine days Doses of this strength would amount to out 0 006 per cent formic aldehyde in the blood, 0 002 er cent. solutions in broth have a noticeably inhibitory tion on bacillus anthracis (Flügge)

4 Chinosol ($C_9H_6NKSO_4$) in doses of 0 002 gramme per 0 grammes body weight almost invariably produced transiry paralysis, 0 0004 gramme to 0 0005 gramme per 100 rammes body weight could be given about every other day r ten days without adverse symptoms, but the weight then ll progressively, although the injections were suspended. his dose amounts to a solution of from 0 005 per cent 0 006 per cent in the blood, the former strength has een found by Benecke[15] to produce an antiseptic effect n anthrax bacilli in nutrient media after an exposure of 24 ours

5 The mixture of formic aldehyde and chinosol was given n 0 5 cubic centimetre doses each drug being represented n a proportion of 0 00028 gramme per 100 grammes body eight. The toxic effects (loss of weight and general ymptoms of malaise) were however, so marked even after wo or three injections that no further experiments were nade

6 Protargol in doses of from 0 0002 gramme to 0 0003 ramme per 100 grammes body-weight every second or third lay produced steady loss of weight from the beginning arger doses occasionally produced paralysis. This repreents about 0 004 per cent solution in the blood. Benario[16] tates that a 0 01 per cent. solution of protargol has no nhibitory effect *in vitro*

7 Sodium taurocholate is the most active antiseptic of the substances found in bile It is however very toxic when injected intravenously in rabbits 0 00005 gramme per 100 grammes body weight injected every other day producing progressive emaciation after five days. The solution in the blood was 0 0007 per cent. The exact antiseptic power of this substance has not, so far as I know, been accurately determined

The conclusions drawn from this series of experiments are —1. That perchloride of mercury oxycyanide of mercury, and protargol cannot be injected intravenously into rabbits in sufficient strength to produce an antiseptic effect lasting over several days 2. That a mixture of chinosol and formic aldehyde is too toxic even in minute doses to be of use for practical purposes 3 That chinosol or formic aldehyde can be injected intravenously so as to produce a solution which would have an inhibitory action *in vitro* 4 That sodium taurocholate can be injected in small doses but that toxic effects manifest themselves after a few days

In the second series of experiments the effects of injections of the above substances on infected animals were investigated. Perchloride of mercury however was not tried as former observers have reported very unfavourably on its action Owing to its toxicity the mixture of chinosol and formic aldehyde was likewise omitted. The anthrax for inoculation was prepared as follows The blood of a guinea pig recently dead from the disease was planted on an agar tube and incubated for 24 hours at 37° C. The purity of the cultivation having been established by microscopical examination a small platinum loop holding about 0 3 milligramme was filled with the growth and transferred to 10 cubic centimetres of broth for 16 hours at 37° C No spores were detected in this growth Six rabbits were then inoculated intraperitoneally with 0 5 cubic centimetre of the cultivation which had been diluted with an equal volume of sterile broth and well shaken up so as to form a homogeneous emulsion The drugs selected were then injected into five of the rabbits in the following proportions oxycyanide of mercury 0 00005 gramme per 100 grammes body weight formic aldehyde 0 0007 gramme per 100 grammes body weight, chinosol 0 001 gramme per 100 grammes body weight, protargol, 0 0004 gramme per 100 grammes body weight, and sodium taurocholate 0 00006 gramme per 100 grammes body weight These injections were repeated every 24 hours, those of chinosol and protargol, however, being reduced to one half the original proportion after the first dose. The oxycyanide, formic aldehyde, and chinosol rabbits were found dead on the fifth day The rest, including the control animal survived Post-mortem examination which included opening the thorax and abdomen under full aseptic precautions and the making of cover slip preparations and agar cultivations from the blood of the heart and spleen showed that all the animals died from anthrax septicæmia. The three remaining rabbits on the eighth day after the first inoculation were re inoculated with a dose of anthrax prepared in the same way as the first only of twice the strength the broth cultivation not being diluted Protargol and taurocholate of sodium were injected in the same proportions as before The taurocholate rabbit lived three days the control rabbit four days and the protargol rabbit four and a half days after the second injection The post-mortem methods and results were the same as in the first three cases.

Another series of six rabbits was then inoculated with the stronger dose of anthrax emulsion in the same manner as on former occasions Five of them were injected daily in the following proportions oxycyanide of mercury 0 00005 gramme per 100 grammes body weight, formic aldehyde, 0 001 gramme per 100 grammes body weight, chinosol, 0 0005 gramme per 100 grammes body weight protargol, 0 0003 gramme per 100 grammes body weight, and sodium taurocholate, 0 00005 gramme per 100 grammes body weight. The injections were repeated daily till the death of the animals, which occurred in the following order oxycyanide of mercury and sodium taurocholate, died after two and a half days, protargol died after three days, formic aldehyde and control died after three and a half days, and chinosol died after four days Post-mortem results showed that all animals died from anthrax In no case was there any evidence of an inhibitory action on the part of the antiseptic.

As in the case of formic aldehyde and chinosol a sufficient dose could be administered to obtain what *in vitro* would be an antiseptic action a further experiment was tried with these substances, the organism chosen being the pneumococcus owing to its more feeble resistance to bactericides This organism was grown from a virulent strain on standardised blood agar tubes one loopful (0 3 milligramme) being diluted 100 000 times in sterile broth and 1 cubic centimetre of the emulsion injected subcutaneously The dose, therefore, was 0 00001 loopful The proportion of the antiseptics injected was formic aldehyde 0 0021 gramme per 100 grammes body weight, chinosol, 0 003 gramme per 100 grammes body weight, and the dose administered three times during the first day On the second day two doses were given of formic aldehyde 0 0025 gramme per 100 grammes body weight and chinosol, 0 0035 gramme per 100 grammes body weight. On the third day the formic aldehyde rabbit received 0 0029 gramme per 100 grammes body-weight twice and the chinosol rabbit 0 0044 gramme the latter animal dying a few hours later The former animal died during the next 24 hours The control died on the sixth day Paralysis was observed after each chinosol injection The post mortem results were positive.

From these experiments the following conclusions may be drawn (1) that rabbits injected daily with non toxic doses of oxycyanide of mercury, formic aldehyde chinosol protargol or taurocholate of sodium are not thereby protected from the usual effects of a previous inoculation of virulent anthrax, and (2) that chinosol and formic aldehyde in large doses (toxic) so depress rabbits infected with the pneumococcus that they die sooner than an untreated animal

Generally then it may be said that at present there is no experimental evidence which would warrant the assumption that the course of a septicæmia in animals can be influenced favourably by the intravenous injection of antiseptic substances and that the only result to be obtained by pressing such a treatment beyond the maximum non toxic dose is to hasten the death of the animal In view of the results described in this paper and those obtained by former investigators it seems useless to continue trying to apply clinically a method which while by no means free from special dangers and difficulties is at present unsupported by any experimental evidence either as to its present advantages or future prospects

INTRAVASCULAR ANTISEPSIS

BY J M FORTESCUE BRICKDALE, M A , M B , B CH OXON

(From the Bacteriological Department, Jenner Institute of Preventive Medicine)

THE idea that drugs might advantageously be administered by direct injection into the circulation was first started by an English mathematician and architect and has had its latest exponent in an Italian Cabinet Minister Sir Christopher Wren in 1656 was the first to carry out the "noble anatomical experiment" and the medical profession has coquetted with the method ever since—exaggerated enthusiasm for it alternating with absolute neglect Ettmüller, Purmann, Major, and Escholtz during the last half of the seventeenth century, and Percy, Majendie Scheel, and Dieffenbach during the first quarter of the nineteenth century gave the method extended trials Since the latter period, Oré and Halford endeavoured to introduce it for special purposes but met with no lasting success, whilst recently Baccelli Landerer, Maguire and others have revived it in connexion mainly with the treatment of bacterial diseases or diseases presumably of parasitic origin That it is possible to introduce small quantities of a large number of substances directly into the veins cannot be denied but that any great advantage can be obtained by such a procedure has never as yet been experimentally demonstrated The advocates of the "Chirurgia Infusoria," as Major called it, have based their opinions as to its merits on various grounds, and it is only with the attempts to carry out one of the recent theories for its application that the present paper will deal. For many years experimenters and clinicians have been endeavouring to apply antiseptic principles to the treatment of septicæmic diseases Baccelli, who introduced the intravenous injection of perchloride of mercury in syphilis (a proceeding which, after prolonged trial throughout Europe, has been practically abandoned as presenting no special advantages) extended his method to epidemic cerebro-spinal meningitis, acute rheumatism, and other diseases notably aphtha epizoötica in cattle His early successes with the last mentioned ailment have not however, been attained by other observers , in fact, it has been conclusively shown that perchloride of mercury injected intravenously has absolutely no effect either in preventing or modifying an attack.[1] The effect was undoubtedly intended to be that of an internal antiseptic but a dilution strong enough to harm any bacteria living in the blood could not be obtained with a non toxic dose of the drug Maguire and Ewart[2] in this country have recently tried to render the lungs aseptic by injecting comparatively large quantities of formic aldehyde and protargol respectively 200 tuberculous patients have been treated by the former method and the results except in severe cases are reported as successful. A solution of formic aldehyde (1 in 100 000 in the blood) can be passed through the lungs for half an hour while Ewart has succeeded in flushing the smaller circulation with protargol of a strength equal to nearly 1 in 500 Of these two methods only the latter can be said *primâ facie* to have any chance of success the formic aldehyde solution being too weak to exert any effect *in vitro* The clinical evidence however is according to both experimenters, encouraging Credé[3] in Dresden has injected a preparation of citrate of silver, but the exact antiseptic power of the solution *in vitro* has not been accurately determined, so far as I am aware and the clinical results are too few in number and too miscellaneous in character to carry much weight.

As against these clinical experiments there is a growing mass of laboratory work which may be said to be wholly unfavourable to the idea of intravascular antisepsis In 1887 Behring[4] found that oxide of silver when injected in non lethal doses into rabbits guinea pigs, and mice infected with anthrax rather lengthened the life of the animals In toxic doses the anthrax bacilli were only rarely found post mortem in the blood and organs

The late Dr J W Washbourn[5] in 1888 injected creoli subcutaneously, but failed to cure either rabbits or mice though fewer anthrax bacilli were found in the animal treated Fischer and Fricker[6] tried intra peritoneal injections of formic aldehyde in guinea pigs inoculate with tubercle, but found that in all cases the contr animals survived those which had received the injections In 1884 Cash[7] succeeded in curing rabbits o anthrax by hypodermic injections of perchloride of mercury The injections were made for some weeks before inoculatio and were not by any means uniformly successful Koch and Behring,[9] who repeated his experiments failed to ge positive results, and Cadéac[10] stated that dogs treated in this way actually had their resistance to anthrax considerabl diminished During the past year Spissu[11] and Serafini made some accurate and extensive investigations with the same drug The former observer determined the maximum non lethal dose for rabbits at 0 0003 gramme per 10 grammes body weight, but found that even toxic doses failed to prevent the growth of anthrax bacilli in the blood Serafini's dosage was 0 00027 gramme per 100 grammes body weight and he also had negative results both with anthra and fowl cholera in rabbits With a view of obtaini further evidence on this subject the following experiment were carried out at the Jenner Institute of Preventiv Medicine during the summer of the past year I planning these experiments I had two objects in view firstly, to test the toxicity of various antiseptics when injected into the veins of rabbits and secondly to discove if any of them exerted an influence on the course of a artificially produced septicæmia. The actual injections were kindly made for me by Dr A Macfadyen

The following substances were chosen for the first series of experiments (1) perchloride of mercury, (2) oxycyanide of mercury, (3) formic aldehyde, (4) chinosol, (5) a mixture of formic aldehyde and chinosol, (6) protargol and (7 taurocholate of sodium In all cases the solutions were freshly prepared for each injection, the substances being carefully weighed on a chemical balance, the injections were made with antiseptic precautions into the marginal veins in the rabbit's ears The idea was so to regulate the doses that a number of injections could be made on successive days not merely one large injection at a given time after infection as was the case in Spissu's and Serafini's experiments In this way I thought it possible that some tolerance of the drugs might be established

1 Five rabbits were treated with perchloride of mercury in various strengths, but even in dilutions of 1 in 2000 doses of half a cubic centimetre repeated at intervals of about 48 hours produced progressive emaciation, while larger doses (six cubic centimetres of 1 in 1000) repeated daily for three days gave rise to diarrhœa and death In the former case the proportion of perchloride of mercury was 0 00001 gramme per 100 grammes body weight, which would approximate to 0 00013 per cent solution of the salt in the total volume of the blood , 1 in 2000 perchloride of mercury being necessary to kill anthrax bacilli in blood serum (Behring[13]) no further experiments were made with this substance

2. Rabbits were found to tolerate oxycyanide of mercury ($HgOHg(CN)_2$) in a proportion of 0 00004 to 0 00005 gramme per 100 grammes body weight which would produce a solution of about 0 0006 per cent to 0 0007 per cent in the blood De la Croix[14] found that 0 00125 per cent was necessary to inhibit the growth of anthrax in broth Larger doses, however, were not found practicable as the animals rapidly lost weight and died

3 Formic aldehyde in 1 per cent. solution can be injected with safety in small doses Two cubic centimetres of a 1 in 65 solution produced in one rabbit an immediate discharge of mucus from the nose and with solutions of this

e food through the pyloric sphincter, thus acting as a lating agent. Perhaps the "cold," too, helped by causing neral relaxation of muscular tone

5 The ultimate recovery of the child without any operation, although the case seemed at one time well nigh hopeless. Indeed, I was sent for one night because the rse thought that the child was dying The recovery also as complete, the child regained his strength and vigour, o trace can now be found of any dilatation of the stomach, any difficulty in the passage of food from the stomach into e pylorus or of any thickening of the latter organ.

PATHOLOGICAL SOCIETY OF LONDON

ullet Wounds of the Intestines —Tuberculosis of the Œsophagus —A Case of Congenital Tuberculosis —Two Cases of Congenital Heart Disease —Cholesteatoma of the Pineal Body

A MEETING of this society was held on Jan. 6th, Mr R J GODLEE, the Vice President, being in the chair

Mr G LENTHAL CHEATLE showed the Lesions in a case of ullet Injury to the Abdomen. The wound was inflicted by Jeffery's modification of the Mauser bullet. It had passed through the cæcum, left the small intestine practically uninjured, and then caused the man's death by inflicting large wounds in the sigmoid flexure from which extravasation of fæces occurred The bullet remained impacted in the skin wound of exit. The wounds of the cæcum were quite free from extravasation and there was practically no perifæcal peritonitis Microscopical sections of the wounds of penetration and emergence demonstrated that extravasation was prevented by the valvular condition of the opening made by the bullet and induced by the different degree of elasticity possessed by the various tissues forming the different parts of the intestinal wall. The most important factor in bringing about this result was probably the muscular coat. The sections clearly showed that prolapse of the mucous membrane could not have had any share in preventing extravasation Incidentally Mr Cheatle pointed out that skin wounds of exit usually showed, at any rate microscopically, extrusion of adipose tissue between the epithelial margins. He showed that the tissue might contain sweat glands in its extruded meshes, and also that skin wounds of exit have a larger subcutaneous hæmorrhage than those of entrance. This case showed (1) that a bullet of low velocity was capable of inflicting as insignificant an injury as one of high velocity, (2) that a bullet might traverse the region occupied by the small intestines without perforating them (3) that an expanding bullet need not, and he believed did not expand when it came in contact with soft parts (4) that the absence of extravasation in small bore bullet wounds of the intestines was prevented not by prolapse or extrusion of mucous membrane, but by the valvular form of the tissue assumed by the track of the bullet, and (5) that the best and often the only means of deciding upon the direction in which the bullet travelled was by making careful microscopical sections of all the tissues struck. This point, Mr Cheatle said, might be of considerable importance in medico-legal questions.—Mr S G SHATTOCK said that he had had the opportunity of examining one bullet wound at the seat of entrance and had been able to find hardly any evidence of injury, the tissue was but little displaced and there was no necrosis.—Dr PURVES-STEWART asked whether Mr Cheatle could give any explanation why the bullet came into the exit wound with the blunt end foremost. He said he had seen one case in which the bullet had entered the skull in the frontal region and had been found in the occipital region of the brain with the nose of the bullet pointing in the direction of the entrance wound. In this case the position was to be explained by the rebound from the inner wall of the skull but such an explanation would not serve in Mr Cheatle's case.—Mr CHEATLE in reply said that it was probable that the bullet had a low velocity at the time of entrance and that it revolved on its long axis and therefore came to lie with its hind end outwards.

Dr W T MULLINGS and Dr F C SHRUBSALL showed a specimen of Tuberculosis of the Œsophagus This condition seemed to be very rare, since no case had been described in the British Isles. The specimen was from a man, aged 50 years, who was admitted to the Brompton Hospital under the care of Dr T D Acland suffering from hydro pneumothorax. During life the only evidence of œsophageal lesion was dysphagia which came on suddenly a few days before death, the pain on deglutition was considerable and was only relieved by swallowing a solution of cocaine. There was no evidence of pharyngeal ulceration, though early tuberculosis of the larynx was discovered. At the necropsy tuberculous lesions were found in the lungs, intestines, right testicle trachea, and great bronchi. The bronchial and mediastinal glands showed no macroscopic evidences of tubercle The extreme upper portion of the œsophagus was not examined. The middle portion showed extensive ulceration over a length of three and a half inches the individual ulcers being oval with their long axis in the long axis of the tube. Below this there were a few scattered ulcers Microscopically typical tubercles with giant cells and tubercle bacilli were demonstrated. The case was one either of extension from the pharynx or a local infection through the sputum, the evidence being more in favour of the latter cause —Dr. P HORTON-SMITH said that he considered that the condition was extremely rare In some 200 necropsies which he had performed on tuberculous subjects he had never met with ulceration of the œsophagus and in some 2500 necropsies performed by Dr S. H. Habershon the condition had been met with on only two occasions.

Dr F W ANDREWES showed three rare specimens which he had recently investigated from amongst the contents of the museum of St. Bartholomew's Hospital and which had hitherto not been adequately described. The first was an apparently authentic example of congenital tuberculosis in man. The specimen consisted of the thoracic viscera of an infant stated to have died shortly after birth—a statement confirmed by the size of the organs and by the fact that the ductus arteriosus was still pervious The tracheal and bronchial glands were much enlarged and caseous and the lungs contained numerous miliary tubercles The histological appearances were characteristic of tubercle. The glandular lesions must evidently have arisen long before birth and it was suggested that infection might have occurred per os by the swallowing of amniotic fluid. The other two specimens were instances of rare forms of congenital malformation of the heart In one there was complete absence of the right auriculo-ventricular orifice, with a double orifice on the left side, the right ventricle being rudimentary the foramen ovale widely patent the interventricular septum perforated by a small aperture, and the ductus arteriosus practically closed. The two orifices connecting the left auricle and ventricle were provided with separate and well formed valve curtains and chordæ tendineæ The possible origin of this rare abnormality was discussed In the second case there existed a thick muscular septum dividing the proper cavity of the right ventricle from that of the conus arteriosus perforated only by a minute aperture admitting a good sized probe. This form of pulmonary stenosis was evidently a true developmental anomaly and not due to fœtal endocarditis

Dr H M FLETCHER showed a Cholesteatoma of the Brain from a youth, aged 19 years who while lifting a parcel on to a van suddenly became unconscious and died 36 hours later in St. Bartholomew's Hospital The tumour which was of the size of a small walnut, was situated in or beneath the velum interpositum, behind and compressing the pineal gland It was hard and had a pearly lustre It consisted of a dense fibrous-looking outer portion with a soft granular core The lining epithelium was of the stratified squamous variety with a well marked corneous layer forming concentric laminæ with abundant cholesterine crystals In the majority of cases described the tumour had been found at the base of the brain. Cholesteatoma was usually regarded as a proliferation of the endothelial cells lining the subarachnoid trabeculæ, but Dr Fletcher was inclined to look upon it as allied to dermoid cysts in origin.—Dr F J POYNTON said that he had seen one case of cholesteatoma in which there were two tumours one considerably larger than the other, situated symmetrically at the base of the brain between the pons and the cerebellum He called attention to the suddenness with which coma and other symptoms developed in cases of simple tumour of the brain —

1609

A CASE OF HYPERTROPHIC STENOSIS OF THE PYLORUS IN AN INFANT, RECOVERY WITHOUT OPERATION

BY H WILLOUGHBY GARDNER M D LOND, M R C S ENG, L.R.C.P LOND,
PHYSICIAN TO THE SALOP INFIRMARY ETC

IN connexion with the paper on this subject which was recently brought before the Royal Medical and Chirurgical Society by Dr E Cautley and Mr C T Dent, and the discussion which ensued,[1] the following case, which occurred in my private practice, seems to be of interest.

The patient, a healthy male and a first child, was born on Jan 30th, 1902 He weighed at birth 8 pounds 8 ounces He was brought up until the illness commenced entirely by the breast and was in perfect health until March 20th, when he began to suffer from diarrhœa At that time his weight was 11 pounds 8 ounces It was then found that the mother, too, was out of health, and her milk was noticed to be very thin Some three weeks previously the nurse had left and since that time it was thought that the mother had been doing too much Notwithstanding treatment both for mother and child the diarrhœa persisted and on March 30th vomiting commenced On about April 10th, as the child had been gradually getting worse, he was finally taken from the breast and various kinds of food were tried—viz, a malted proprietary food, bread jelly, unsweetened condensed milk, and peptonised milk, all diluted to varying degrees All, however, caused more or less vomiting usually about half an hour after they had been taken, except in the case of the bread jelly, which, though prepared with the utmost care, was generally returned at once The child at first steadily, and then rapidly lost weight On April 24th his weight was 9 pounds 12 ounces and a note was made that he had lost nine ounces in the last five days All food was then stopped except whey With the increase of the sickness the diarrhœa had ceased and the bowels had become constipated, the scanty motions being green and slimy and very offensive. On the 26th the child was apparently sinking He was then ordered to be fed with a teaspoonful of whey every 20 minutes. It was found that brandy in any form and even in the smallest quantities was immediately vomited About this time visible peristalsis of the stomach was first noticed The cardiac end of the stomach would form into a ball almost of the size of a small Tangerine orange and this ball would pass as a wave obliquely across from left to right and slightly downwards until it reached the site of the pyloric orifice where it would stop and, as it were melt away This recurred in quick succession and could generally be perceived whenever the abdomen was laid bare, or if not it could always be provoked by the application of a cold hand or by any slight stimulation

On April 29th I asked my surgical colleague, Mr L J Godson to see the child with me He discovered on deep palpation a somewhat soft ill defined, rounded swelling which was situated behind the left rectus in the region of the pylorus and seemed rather smaller than a pigeon's egg This tumour was often afterwards searched for and could generally, but by no means always be felt. The vomiting was at this time less owing to the extremely careful feeding but the child was still losing weight The question of operation was therefore considered and it was put to the parents that an operation might be the only means of saving the child's life It was not however, strongly urged partly because we were ignorant as to the pathology of the condition and as to the significance of the tumour which we felt, and partly because we did not then know that any such operation had ever been performed with success (An exploratory operation with the possibility of gastro-enterostomy was what was in our minds.) The parents however decided to wait a little longer and very gradually the child began to improve The lowest weight recorded was 9 pounds 5 ounces on May 4th From that time the vomiting, though still very troublesome and occasionally severe gradually became less frequent The bowels for a long time remained obstinately constipated and had to be relieved by olive oil enemata. Whey was for a long time ordered as the principal diet, a little malt was soon added, dissolved in the whey, then barley water and maltine were given occasionally as a change Gradually a little raw meat juice, or sometimes a little white of egg, was cautiously added to the food and the quantity was gradually increased from one to two three, and four teaspoonfuls at a time, the interval between the feeds being prolonged. Later a few drops of cod liver oil or of cream were sometimes added and a little grape juice but for a long time care was taken not to give anything that could possibly leave any residue The addition of a little milk to the food was tried but it was found not to suit The sickness gradually abated and the child slowly regained weight until about the beginning of June when he caught a severe cold and developed a troublesome cough He then rapidly lost weight again, falling in a week from 9 pounds 8½ ounces to 9 pounds 2 ounces—the lowest weight registered during the whole of his illness Curiously enough, however, when the cough and cold commenced the vomiting ceased and diarrhœa appeared in place of constipation. When he recovered from the cold he rapidly increased in weight and he was never again troubled with sickness On June 22nd it was no longer considered necessary for anyone to sit up with him at night Since the middle of August he has never had a bad symptom of any kind Early in October he was successfully vaccinated. He is now a healthy looking child plump and firm of flesh, the only point against him being that he has as yet cut no teeth When last weighed at the age of 10½ months he scaled 20 pounds—two and a half pounds above the average

This case appears to present all the characteristics of those described by Dr Cautley and Mr Dent under the name of "congenital hypertrophic stenosis of the pylorus"—viz, (1) the obstinate vomiting, (2) the constipation, (3) the wasting, (4) the visible peristalsis of the stomach, and (5) the presence of an ill defined tumour in the region of the pylorus As to whether the stomach was dilated or not I cannot say not being sufficiently familiar with the normal size of an infant's stomach, it certainly was not greatly dilated, but it was noticeable that sometimes when the child had not been sick for some hours he would suddenly, to the despair of his mother and his nurse bring up seemingly all the food he had taken during that time just as an adult often does when suffering from a dilated stomach.

The noteworthy points about the case appear to be the following —1. There seems no possible doubt that the affection was not congenital Not only was the child at birth two pounds above the average weight (8 pounds 8 ounces as against 6 pounds 8 ounces, the average), but at the age of seven weeks, when the illness commenced, he had reached 11 pounds 8 ounces—three pounds above the average, which is given as eight pounds, or, to put it in another way he had during those seven weeks gained three pounds in weight, the average gain during that time being given as 1 pound 12 ounces. There could hardly therefore, during those first seven weeks of his life have been anything wrong with his digestive apparatus

2 The disease seems to have been caused at first by there being something wrong with the mother's milk owing to the mother herself getting out of health It would seem as if the milk as it became thin and poor gained at the same time some irritating quality The first effect of this was the diarrhœa, which had lasted some ten days before the vomiting commenced, then came the spasm of the pyloric orifice, probably at the same time as the vomiting It would almost seem as if the pylorus was trying to shut out the noxious milk and to prevent it entering the bowel. One supposes that the spasm thus induced caused after a time hypertrophy of the muscular coat of the pylorus, and so produced the thickening which could be afterwards felt as a tumour This muscular hypertrophy and probably also an irritable condition of the mucous membrane causing ready spasm would, in their turn be the cause of the increased peristalsis and the vomiting and so the trouble would persist even after the food had been changed.

3 The fact that improvement only commenced when everything that could possibly have left any undigested residue had been discontinued as food and when only very small quantities at a time were given. The pyloric sphincter would then get almost perfect rest.

4 The curious fact that what completed the recovery was the cold and the cough which accompanied it, though the child himself was greatly reduced in weight and strength thereby It occurs to me that the cough must have forced

---

[1] THE LANCET Dec 20th 1902, pp 1679 and 1693

Cave showed that often it was of a septic nature, the infective agent reaching the system through the alimentary canal. 3. Arthritis deformans or monarticular arthritis. This, probably, was also microbic in origin, in which, however, trauma and a debilitated constitution played an important part. The various forms of spondylitis deformans and their relation to osteo-arthritis, gonorrhoeal arthritis, and affections of the meninges were alluded to. In conclusion Dr. Dreschfeld dealt with the treatment of chronic rheumatoid arthritis.—Professor G. A. WRIGHT spoke of the need for an entire revision of the nomenclature of joint diseases and the desirability of abolishing all names with rheumatism in them. He laid stress upon the frequency of specific joint diseases of various kinds, septic, exanthematous, and others.—Professor J. DIXON MANN, whilst fully admitting the micro-organismal causation of acute rheumatism, could not accept the view that streptococci which were capable of producing ordinary septicæmic conditions were the micro-organisms in question. The characteristic feature of acute rheumatism was that the fibrous structures in relation to the joints, the heart, and the lungs were attacked by a most active type of inflammation which led to effusion and to fibrinous exudation, but which systematically stopped short at that and rarely went on to the formation of pus. Whereas when the system was invaded by micro-organisms of the type in question the formation of pus along with other characteristic manifestations of the septic state as *ordinarily understood* were distinctive characteristics. On these grounds he doubted the efficacy of Menzer's serum obtained from animals that had been inoculated with cultivations of streptococci which had been scraped from the tonsils of patients in the early stage of acute rheumatism. Many cases that simulated acute rheumatism partook of a septic character and were probably of a mixed etiology.—Dr. A. T. WILKINSON considered acute rheumatism to be a definite disease due to a micro-organism in which, however, as in diphtheria, a mixed infection might occur. The mobility of the joint lesion was the strongest indication for the use of the salicylate. He agreed with Dr. Dreschfeld in preferring moderate doses and always prescribed with it tincture of nux vomica and citrate of potassium. In single rheumatic joint lesions and in the solitary gonococcal swellings in which the disease took the joint on lease small local blisters usually gave most relief. Dr. Wilkinson also referred to a case of acute herpes following the branches of the right anterior crural nerve in which changes resembling those seen in subacute osteo-arthritis developed in the knee-joint but gradually subsided in the course of six months.—Professor R. B. WILD considered that the name rheumatic arthritis covered a group of pathological conditions and that with their present knowledge an accurate differentiation of the members of the group was impossible. One member, however, acute rheumatism or rheumatic fever, appeared to be more sharply defined and differed in many ways from the others in its course. Among the points of difference attention was drawn to the type of the fever and especially its comparatively slight depressing action on the central nervous system, secondly the peculiar tendency of the arthritis to affect joint after joint and rapidly to disappear, the evanescent character of the arthritis in any one joint being comparable to the acute onset and rapid disappearance of the lesions of the skin in urticaria, a disease which was produced by absorption of toxic substances from the alimentary canal, and thirdly the very slight anatomical lesions found in the inflamed joints when examined post mortem were worthy of note. With respect to treatment the salicyl compounds in full doses certainly relieved the symptoms and the probability of their having a specific action upon the rheumatic toxins was suggested by the *fact* that similar good effects were not produced by closely allied chemical compounds such as benzoic acid, pyrocatechin, or even the meta- and para-hydroxy benzoic acids which were isomeric with salicylic acid.—Dr. C. W. BUCKLEY said that a damp subsoil was a most important factor in the production of rheumatoid arthritis and considered that a change of residence should be made if possible to a place with a dry soil and a bracing climate, or in default of this as long a stay as was possible should be made in a health resort of this type. Balneological treatment was of the utmost value when combined with such climatic factors. Of the many forms of electrical treatment now in vogue he had found the constant current bath to be by far the most useful.

Mr. W. THORBURN showed a case of Charcot's Joint Disease of the Knee developed after a slight injury and preceding other ataxic symptoms which had been treated by arthrodesis.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases and Specimens.—Squint.

A MEETING of this society was held on Dec. 18th, Mr. RUSHTON PARKER, the President, being in the chair.

Dr. K. A. GROSSMANN showed a case of Congenital Malformation of the Iris in both Eyes. The patient, a poorly developed boy aged 14 years, was subject to nervous twitchings of the head and horizontal nystagmus. Microcornea was present in both eyes. The right iris was represented by a narrow band stretching across the base of the lower quadrant. In the left eye only the lower quadrant was missing. From the presence of chorio-retinitis, nasal bone changes, and the teeth, a diagnosis of specific intra-uterine uveitis was made. Dr. Grossmann also demonstrated a case of Peculiar Choroidal Traumatism.

Mr. F. T. PAUL showed a gardener aged 59 years whose Right Subclavian Artery he had Ligatured in the Second Part for an Aneurysm of the Axillary Artery extending up to, and involving, the third part of the subclavian. The patient had suffered from syphilis and had been subjected to local strain of the artery. There was evidence of extensive endarteritis and the vessel when ligatured was considerably diseased. Catgut sterilised in xylol was used and was not drawn tight. The wound healed by first intention, the aneurysm filled with firm clot and was now, two months after operation, shrinking satisfactorily.—Sir WILLIAM H. BANKS had seen three cases of traumatic axillary aneurysm—a disease of by no means frequent occurrence. The first case occurred in a sail maker and distinctly followed a strain, but the vessel might quite well have been atheromatous. Two years after successful ligature of the subclavian artery it was impossible to know that there had been any aneurysm. In the second case degeneration of the artery was unlikely as the patient was a young healthy man, the condition being due to a railway crush. The aneurysm had spread into the neck and was as much subclavian as axillary. With the aid of his colleague, Mr. Paul, Sir William Banks made a strenuous attempt to ligature the first part of the left subclavian artery in the thorax, the pleura was a good deal injured and the patient died from pleurisy. In the third case the aneurysm resulted from injury produced by an attempt to reduce a dislocated shoulder. At the operation in which he assisted Dr. Nathan Raw the pectorals were divided and a temporary ligature was placed at the highest point of the axillary artery, the aneurysmal sac was opened, and the vessel was tied above and below. Complete recovery followed.—Dr. E. MOLYNEUX had discovered the aneurysm in the case brought forward by Mr. Paul quite casually. It had caused no discomfort whatever. The patient had for years suffered from gout and he thought that the gouty diathesis had more to do with the case than had syphilis.—The PRESIDENT had seen three cases and in all a traumatic factor was present.—Dr. PUTNAM also spoke and Mr. PAUL replied.

Dr. B. F. P. MACDONALD described a case of Multiple Rodent Ulcer. There was no history of syphilis in the patient, a woman, aged 45 years, or of cancer in the family. The ulcers were seven in number situated over the left mamma, the sternum, and above the left clavicle. The condition had existed untreated for two years. He had been unable to trace a record of any similar case. The patient showed all stages, from the initial node to the final typical crater like ulcer. The diagnosis of rodent ulcer was based on (1) the slow growth, (2) the good health of the patient, (3) the marked tendency to heal, (4) the non-implication of the axillary glands, and (5) the evidence of the microscopical sections prepared by Dr. W. Anderson and others.—Mr. PAUL said that the histological characters were those of glandular carcinoma, and if it was certain that the disease had originated in the skin they might have been consistent with the appearances presented by some varieties of rodent ulcer. On seeing the patient, however, he had no hesitation in deciding that it was a rare form of ulcerating cancer of the breast.—Sir WILLIAM BANKS and Dr. ANDERSON spoke and Dr. MACDONALD replied.

Mr. EDGAR A. BROWNE read a paper on Squint in the course of which he said that in the history of squint there

Dr F E BATTEN said that he believed the sudden onset of symptoms in cases of non malignant tumour of the brain was often due to the rapid increase of *intra ventricular* pressure owing to the occlusion of the iter —Dr C OGLE said that a few years ago he had shown two specimens of tumours of the pineal gland In both these cases the prominent symptom had been continual drowsiness, in one case the boy slept for several weeks. He attributed this drowsiness to the fact that fluid tended to increase in the ventricles He pointed out that the other symptoms connected with tumours in this position were total blindness dilatation of the pupil, and an absence of reaction of the pupil to light. He stated that in more than one of these cases it had been noted that there was an unusual development of the genital organs —Mr GODLEE referred to the case of a man who had a melanotic sarcoma of the brain, whilst in hospital the man obtained a considerable quantity of whisky, which he drank, and rapidly passed into a state of coma and died He thought that the disturbance of the vascular supply of the brain was the cause of the acute symptoms in the case and that in all probability the onset of acute symptoms in other cases of tumour of the brain had a similar explanation —Dr FLETCHER, in reply, said that he thought that the rapid onset of symptoms was due to a vascular disturbance, and in the case recorded extreme drowsiness had been a marked symptom

MANCHESTER MEDICAL SOCIETY

Rheumatic Arthritis and other allied Joint Affections — Exhibition of Case

A MEETING of this society was held on Dec 3rd, Dr THOMAS HARRIS, the President, being in the chair

Dr J DRESCHFELD opened a discussion on Rheumatic Arthritis and other allied Joint Affections and their treatment He pointed out that the subject naturally divided itself into acute and chronic joint affections Of the acute variety the first place was occupied by acute rheumatic arthritis Recent observations had thrown considerable light on the etiology of this affection, though a good deal still remained obscure Most pathologists and clinicians were now agreed that it was an infectious disease but the question whether it was due to a pathogenic micro-organism or whether more than one micro organism might give rise to the same symptom complex, or whether it was due to a non specific micro organism which only under certain hereditary or predisposing conditions became active, was still a disputed point Recent observers had looked upon the tonsils as the portals of entrance of the micro organism causing acute rheumatic arthritis, and the observations of E Meyer Wassermann, and more recently of Paine and Poynton and Menzer had shown the presence of a streptococcus in the form of a diplococcus in the tonsils of patients affected with acute rheumatic arthritis, which could be cultivated and when injected into rabbits produced lesions such as they saw in rheumatic fever As yet, however, one could not look upon these diplococci as the pathogenic organism of acute articular rheumatism as pointed out by Menzer [1] for other micro organisms had produced the same results, the diplococci described by the various observers showed marked morphological differences and diplococci found in the healthy tonsils and in the tonsils affected with angina and other affections had occasionally when injected into animals produced similar lesions, though it must be observed that Widal and Besançon in a very large series of experiments obtained mostly negative results It must further be observed that in some cases the injection of the streptococci obtained from the tonsils produced at times septic and at other times pyæmic lesions It would appear from these experimental data that though the exciting cause in acute rheumatic arthritis was a micro organism, special favourable conditions depending on an inherited or some peculiar constitutional predisposition or some accidental causes (exposure to cold, to damp &c.) played a prominent part in the causation of acute rheumatic arthritis and favoured the entrance of the micro organism into the blood. The importance of these secondary causes should not be overlooked The experimental researches on this subject had further shown that acute rheumatic arthritis septic arthritis, and pyæmic or suppurative arthritis were more closely related than was at one time supposed and supported the clinical evidence, such, for example, as was shown in the relationship between rheumatic or papillary endocarditis and septic endocarditis. The treatment of acute rheumatic arthritis offered little scope for discussion The salts of salicylic acid were given, they reduced the temperature, relieved the pain, caused a diminution of the swelling, and were said to increase the elimination of uric acid, but they did not shorten the duration of the disease, and did not prevent relapses, and unless alkalies in fairly large doses were given also endocarditis often occurred Local treatment was essential. One form of acute arthritis was especially alluded to in which often the wrist and the ankle became affected and in which besides excessive pain there were a good deal of inflammatory subcutaneous œdema and inflammation of the sheaths of tendons The disease was very obstinate to treatment and often left the joint ankylosed Davies-Colley described this affection occurring in women affected with leucorrhœa. It was a septic arthritis, often due to gonorrhœa, but was occasionally found independently of gonorrhœa, in some rare cases most of the joints might become involved. Acute osteo-arthritis was no doubt a rare affection, but occasionally cases were seen in which there were marked pyrexia, profuse and acid perspiration swelling and pain of the joints, and in which the joint, instead of returning to its normal condition, showed the appearance seen in osteo-arthritis In the present state of their knowledge it was impossible to say whether there was a double infection or whether the disease was primarily one of osteo arthritis The infective arthritis of fevers was next dealt with. Pneumonia, typhoid fever, scarlet fever, diphtheria, small pox influenza, and cerebro-spinal meningitis were sometimes accompanied or followed by an acute swelling and pain of one or more joints The physician had to deal here with various affections: 1. A toxic affection, due to a toxin Some doubted the existence of a toxic arthritis but that such an arthritis existed was shown by the arthritis sometimes following very soon after the injection of antitoxin serum in diphtheria. 2. An arthritis due to the pathogenic micro-organism, as in the cases of *pneumococcal* arthritis described by Cave and Nathan Raw and in some of the reported cases of arthritis in typhoid fever 3 A mixed infection—the effusion into the joint, which might be serous or purulent (pyæmic) containing septic micro organisms 4 True rheumatic arthritis as a complication of the primary infective fever Occasionally, as in typhoid fever the vertebral column might be affected (typhoid spine), characterised by excessive pain and stiffness of the vertebral column this again, being sometimes a nervous affection and at other times a purely toxic affection, at other times there were distinct osteitis and periostitis Gonorrhœal arthritis in its various types was alluded to. Occasionally the vertebral column was also affected Dr Dreschfeld next considered chronic affections, first describing chronic rheumatic arthritis In most persons who had had acute rheumatic arthritis the joints assumed again their normal appearance, *occasionally* however, the smaller joints formed a spindle shaped swelling and remained so permanently, in a few cases with a marked family history of rheumatism the symptoms of rheumatic arthritis came on slowly and insidiously, the joints became stiff and painful. the muscles in the neighbourhood of the joints underwent atrophy marked deformities of the hands and feet ensued, and the patient might become quite crippled The distinction in such a case between rheumatic arthritis and rheumatoid arthritis was almost impossible Such differences as had been pointed out by some observers were scarcely enough to differentiate them He then referred to chronic rheumatoid or osteo arthritis a chronic disease in which one or more joints were affected with marked changes in the cartilage and bones of an atrophic or hypoplastic character and atrophy of muscles and resulting in marked deformity of the joint Various affections had been classified under this head 1 Heberden nodules It was very doubtful whether this was osteo-arthritis In some cases the affection was true gout, in others the lesion was a trophic one, due to overstrain and a general debilitated state of the system Still described two cases in children who had congenital syphilis. 2. The general progressive osteo arthritis Most would agree with Garrod that more than one affection was included in this group The older observations of Wohlmann, Baumtgen and Baxall and the case described by Still pointed to its infectious nature, the more recent ones of

---

[1] Die Aetiologie des Acuten Gelenkrheumatismus Berlin 1902.

Mr HAROLD J STILES showed the following cases — 1 A boy, aged eight years after Operation for Hydatid Cyst of the Liver The patient lived in Shetland and had been recommended by Mr Watson Cheyne who had diagnosed the case. The abdomen was opened by a vertical incision three inches in length midway between the edges of the right rectus On palpating the liver it was found to contain a large cyst. The surface of the liver was then stitched in a circle to the parietal peritoneum and posterior layer of the rectal sheath by a series of looped sutures Inside these a continuous circular suture was applied, so as to unite the surface of the liver to the cut edge of the peritoneum In this way an area of the anterior surface of the liver measuring two inches by one and a half inches was completely shut off from the general peritoneal cavity The wound was stuffed with iodoform gauze A week later the stuffing was removed and the cyst was opened. A large quantity of clear fluid escaped and on introducing the finger the cyst was found to be of the size of a child's head After all the fluid had been evacuated the cyst wall partly detached itself spontaneously and was removed A long empyema tube was employed to drain the cavity On the evening of the operation a rash somewhat resembling measles appeared all over the body, as happens frequently after the aspiration of a hydatid cyst. This rash lasted for ten days The discharge was at first copious and consisted of blood stained mucus Later the mucus was deeply stained with bile and gradually diminished in amount until the tube was removed in the fifth week after the second operation. 2. A girl, after Operation for Congenital Urinary Umbilical Fistula. The parents were first cousins and one of the other children had supernumerary digits A sound introduced per urethram could be passed to within an inch of the umbilicus and there rotated from side to side. There was evidently a fusiform extension of the bladder upwards almost to the umbilicus rather than a mere patency of the urachus The operation consisted in making a mesial incision three inches in length commencing just below the umbilicus An attempt was made to strip the peritoneum from the posterior surface of the upper part of the bladder but it was found that the serous membrane was too thin and adherent to allow of this being done. The abdomen was then opened and the upper part of the bladder was drawn well out of the wound Two intestinal clamp forceps were then applied to the bladder, the one below the umbilicus and the second fully an inch lower down The intervening portion was then cut across just below the upper clamp Both ends of the divided bladder were then closed with a double row of silk sutures, the mucous membrane not being included The clamps were found of great service in checking bleeding and in keeping the parts in good position. After removing them the edges of the parietal peritoneum were so united as to retain the sutured stump of the bladder as far as possible outside the peritoneal cavity The abdominal wound was closed and a strip of iodoform gauze from the sutured bladder was left protruding A self retaining catheter was kept in the bladder for a fortnight and the recovery was uninterrupted. Mr Stiles brought the case before the society on account of its rarity and the infrequency of operation in such cases 3. A girl, aged three years after Intestinal Anastomosis for Stricture of the Lower End of the Ileum due to tuberculous disease of the ileo-cæcal region. The symptoms had been weakness, enlargement of the abdomen diarrhœa, vomiting and "noise in the child s abdomen" Resection in so delicate a child was deemed inadvisable. The only other alternative was to short-circuit the ileocæcal region by establishing a lateral anastomosis between the ileum and the ascending colon. This was done and the child made an uneventful recovery Subcutaneous saline infusions were given twice daily for the first three days and seemed of much service in improving the pulse and preventing thirst. Twelve weeks after the operation the child had improved greatly in her general health. Vomiting and diarrhœa had ceased, the tumidity of the abdomen had gone, and there was no exaggerated peristalsis The enlargement of glands had also disappeared, no doubt due to the rest given to the diseased bowel by the short-circuiting

Mr F M CAIRD exhibited a young man who had received a Bullet Wound on Oct. 24th, 1901 The entrance wound was situated three inches below the right anterior iliac spine His early symptoms were frequency of micturition and hæmaturia. His bladder was carefully sounded but no bullet was discovered. In the hospital at Netley an x ray photograph was taken and showed the bullet *in situ* in the pelvis On admission to the Edinburgh Royal Infirmary he suffered from dysuria and tenderness of the right testicle He found that the process of defecation was easiest while in the reclining position as compared with sitting or squatting When under an anæsthetic the bullet could be felt neither digitally nor by the sound The abdomen was opened and low down in the recto-vesical pouch the bullet was felt and seen to be covered with glistening peritoneum It was removed and was found to be crusted over with phosphates showing that it had been partly in the bladder A good deal of difficulty was experienced in suturing the wound so low down After a somewhat complicated convalescence the patient was now well

Dr W ALLAN JAMIESON showed a case of Xeroderma Pigmentosum after treatment by the x rays The patient was a little girl, the younger of two children Both suffered from xeroderma The child began to develop freckles at the side of the nose when about a twelve month old. Later telangiectasis and whitish spots began to develop on the face The disease had now extended to the hands and wrists There were no other signs of disease When seen on Oct 1st there was an epitheliomatous growth on the tip of the nose of about the size of a sixpence and numerous warty growths were scattered over the face Treatment by the x rays was then commenced, and up to the present the patient had had 34 exposures of five minutes each applied to the face and 13 exposures to the right hand The epitheliomatous growth on the nose and all the warts on the face had disappeared under the action of the rays. An x ray dermatitis was produced, the nose was now whiter than the rest of the face and there was a marked improvement of the right as compared with the left hand Such a case demonstrated (Dr Jamieson said) that the x rays were not the ordinary actinic rays of the spectrum, for the latter tended to increase pigmentation in the skin

Dr T F S CAVERHILL exhibited several tuberculous patients to show the beneficial results of Sanatorium Treatment on Nordrach lines He stated that their own climate was quite well adapted for the cure of such cases and that hygienic measures alone were efficient to obtain cures

Apparatus and card specimens were exhibited by Dr BRUCE and by Dr A. MILES

WINDSOR AND DISTRICT MEDICAL SOCIETY —The third meeting of the session of this society was held on Dec 17th, Mr W B Holderness, the President, being in the chair —Cases and specimens were shown by Mr J O Skevington, Dr P J A. Seccombe Dr C R. Elgood, and Mr James Startin and Mr A W Wigmore —Mr Startin read a paper on the History of the Early Application of the X Rays to cases of Lupus, Rodent Ulcer, Psoriasis, Eczema Acne, and other Skin Diseases by Dr F H Low and Dr J H Sequeira of London Dr G M Lowe of Lincoln, and Professor Schiff and Professor Reund of Vienna, and also referred to his own and Mr Wigmore s work at the London Skin Hospital since 1898 He then described the technique of the treatment After alluding to the action of the x rays on micro-organisms, he proceeded to give an account of the histology and pathology of the skin after exposure to the x rays as described by Mr G Pernet and Dr M Stephen Mayou and the observations made by himself and Mr Wigmore were detailed He next alluded to the physiological effects of the direct spark discharge and high frequency currents and the effect of the x rays on various diseases of the skin Finally after referring to the notes of the cases that had just been exhibited and demonstrated to the members he read a report detailing the result of a year s cases that had been treated at the London Skin Hospital with more or less good results. The number of exposures amounted to 2700 —Mr J H. Tomlinson read a paper on the Present State of Knowledge of the Physical Nature of Roentgen Rays He referred in the first place to the spectrum of ordinary light and showed experimentally that the infra red rays could influence a radiometer through a sheet of ebonite quite opaque to visible light He then described the chief properties of the ultra violet rays—viz, their chemical activity, including their action on photographic plates, their power of exciting phosphorescence and fluorescence, their power of discharging an electroscope charged with negative electricity, and their therapeutic action in lupus, were two eras—the era of Diffenbach who with his followers recognised the obvious misplacement of the eye in relation to the palpebral aperture and remedied the deformity by cutting the (supposed) offending muscle Subsequent improvements in technique had rendered it possible for anyone with a moderate degree of skill in ophthalmic surgery to turn an eye in any desired direction. Indeed so successful in appearance were operations on the muscle that squint was regarded as a muscular affection and innovations in treatment were regarded with suspicion. There was no probability that operations for squint would be discarded in any reasonable length of time—indeed, they must always remain useful in neglected cases—but they were purely empirical proceedings and were sure to give way before a rational knowledge of causation The era of Donders was that of the slow coördination of exact observation of actual facts and their relative importance that constitutes science Donders's "theory" was often spoken of, as other "theories" were, as if it were something outside the range of practice From Donders would proceed the rational treatment of the future He bequeathed two legacies, one a generalisation that hypermetropic eyes squinted towards the mesial line and that myopic eyes squinted out. This remained true and the measurements afforded by the Maddox rod of small degrees of latent squint (or heterophoria) tended to show that the rule had a wide application. But his explanation of why hypermetropic eyes squint was probably only partially true But Donders effectually drew attention to the optical nature of squint The muscles were not at fault. Their contraction was due to their motor centres causing them to perform their natural functions and they had to search for the cause that set the centres in action Squint was not a disease. Its onset was regular, always at the same period of life, always on the same lines and in the same stages It was an accident of development The stages were (1) potentiality—a period when every child whose ocular development was not proceeding regularly might pass into (2) periodicity—when squint took place invariably under excitement or strong desire to see, (3) habitual, when fixation with one eye only was the rule but when parallelism was likely to be restored in sleep, under chloroform, &c—from this two different developments might occur (4) a secondary periodic stage not mentioned in books, ending in recovery, or (5) a stage of permanent deformity involving distortions of the capsule of Tenon, &c, and demanding operation for cosmetic considerations Attention had been too strongly fixed on convergence as the essential phenomenon of squint, but it was the last link in the chain of events An intimate relationship was found to exist between amblyopia and squint. The hypermetropic eye was an incomplete eye and its nervous elements might in certain cases be reasonably supposed to be that of a slow development The sense of vision required practice as well as natural endowment, and if from high hypermetropia or astigmatism one eye was more deficient in clearly formed images than the other, it was likely to lose its instinctive desire for sharp focussing and to become poorly developed from want of exercise, like any other function There was no sense of diplopia when there was a clear image in one eye and a blurred image in the other Hypermetropia was not *the* cause of squint but exhibited the most favourable conditions, especially in the matter of exercising the muscles of convergence. Therefore squint might equally occur in young myopic eyes before the internal recti had lost their preponderating power, if the other conditions were fulfilled Squint, therefore, was a failure in a peripheral sense organ to acquire its complete function, leading to independent and uncontrolled action of the motor centres of the internal (and, in fact, superior) recti Initially nothing took place but what was natural but in later stages deformities and secondary changes became developed Treatment had for its objects restoration of desire for (1) distinct vision, (2) binocular vision, and (3) diminution of accommodation effort. Directions for attaining these objects were given. The obstacles to success were numerous and difficult to overcome. Prevention of squint could hardly be expected till the general practitioner coöperated with the specialist and superintended the treatment in the homes and supervised the ocular hygiene of children in schools —Mr R J Hamilton urged the earliest discovery of, and therefore treatment of children with an unusual degree of hypermetropia Full correction by glasses and operation at an early age were recommended. Stereoscopic exercises, though scientifically sound, could not in practice be carried out.—Dr Grossmann said that there was not the slightest doubt that Donders's explanation was perfectly correct for some cases, but for some only Hypermetropia existed, it was true, in the majority of cases of squint, but also in the majority of non squinting eyes Squint also occurred in myopia (converging concomitant squint). Vision was developed after birth and thereupon depended the importance of the educational treatment. The relationship between accommodation and convergence was completely an acquired one in man, so also was binocular fixation The treatment of convergent squint should be threefold—by glasses, by educational methods, and by operation —Mr Richard Williams could only accept Donders's theory of the causation of squint in a very partial degree To him squint was essentially the result of deranged nerve impulses and hypermetropia played only a minor part. As to the educative treatment, he thought that the result was nothing like commensurate with the trouble involved and patients were mainly interested in getting their eyes "put straight."—Dr Edgar Stevenson said that he first became acquainted with Mr Browne's ideas when he was his house surgeon and he regarded them as heterodox But he had lately had an opportunity of studying this subject and had been struck especially by the practical results attained. He instanced the case of a girl aged 15 years, in whom treatment had been begun at the age of 11 months and in whom the cosmetic results were perfect He was convinced that the views were in the main correct and that the treatment was the most advantageous to the patient, however tedious and difficult it might seem —Mr Hugh E Jones, Mr C H. B Shears, Dr J J O'Hagan, Mr T H Bickerton, and Dr J H Abram also spoke, and Mr Browne replied

MEDICO CHIRURGICAL SOCIETY OF EDINBURGH

Exhibition of Cases and Specimens

A special clinical meeting of this society was held on Dec 7th, Dr W Craig the Vice President, being in the chair

Dr D Chalmers Watson exhibited several patients to show the Results of Treatment by a Preparation of Bone Marrow Two children suffering from ichthyosis simplex were shown on whom the treatment had just been commenced Another was a case of severe generalised eczema in a man, a plasterer by trade, who after five or six weeks of this local treatment had been cured. Two cases of impetigo had benefited by the bone marrow and a case of widespread psoriasis of 20 years duration in a man was giving fairly satisfactory results though slow in comparison with the other cases shown Dr Watson enunciated two theories in explanation of the beneficial results of the local application of bone marrow

Dr H Alexis Thomson demonstrated two cases of Chronic Gastric Ulcer with Pyloric Obstruction treated by Gastro-enterostomy The younger patient, a male, aged 23 years, had suffered from gastric troubles for about two and a half years The other patient was a man, aged 53 years, who had shown gastric symptoms for 10 years Severe hæmatemesis had occurred with signs of pyloric obstruction and cumulative vomiting every second day Both patients had increased in weight to a great degree since the operation

Dr Byrom Bramwell exhibited a case of Tabes in a man aged 50 years The patient first came under observation in April, 1901, and had then symptoms of pre ataxic tabes. He had contracted syphilis 18 years previously and suffered from lightning pains and diplopia. The gastric crises at this time were very severe and rectal feeding had to be carried out He again presented himself in October, 1902, when he was reduced to a skeleton, the crises had occurred every second day during the preceding six months He had lost 3 stones 2 pounds within four months and on Nov 7th weighed only 7 stones 9½ pounds The patient had been subjected to x ray treatment applied to the dorsal part of the spine for five minutes each day This treatment had resulted in an extraordinary improvement. The crises had practically disappeared and in one week he gained 10½ pounds. He had gained 2 stones 4½ pounds since Nov 7th At the present time he partook of ordinary hospital diet. How much the improvement might be due to merely psychical effects it was impossible to say

Gardner (Bournemouth), Dr F Bagshawe (Hastings) Dr G A. Leon (Sidmouth) and the President, and Dr Lewis replied.

CHELSEA CLINICAL SOCIETY —A meeting of this society was held on Dec 16th, Dr C C Gibbes the President, being in the chair —Mr A. F Penny read a paper on Oral Sepsis as a Factor in the Causation of Disease. He referred to the extraordinary manner in which local septic conditions in connexion with diseased teeth were overlooked. Books on medicine impressed on the student the importance of examining the teeth and gums in cases of suspected lead poisoning, syphilis, scurvy, and rickets but with this passing comment they dismissed the subject. Oral sepsis was the commonest and most noxious of all forms of infection in rich and poor alike. The organisms in connexion with dental cario-necrosis were pus forming organisms of a most virulent type and the infection was of a mixed character The most marked effects of oral sepsis were to be found in the stomach and the intestines. Cases were related illustrating the extraordinarily beneficial effect produced in chronic dyspepsia by remedying the oral septic condition, and stress was laid on the advisability of examining the teeth in every case The matter was of great importance from a surgical, medical, and dental point of view The surgeon took every possible precaution, as he imagined, to render his patient aseptic before operating and performed operations of the gravest character on the stomach and intestines while the patient s mouth was septic and full of necrotic teeth. The dentist extracted teeth and left open wounds in a place which was most prone to infection. Cases showing the grave toxic effects were described, including a case of what at first sight appeared to be subacute rheumatism but which cleared up rapidly after the mouth had been rendered aseptic.—A discussion followed.

TORQUAY MEDICAL SOCIETY —A meeting of this society was held on Dec. 18th Dr F D Crowdy, the President, being in the chair —Mr H T Newling showed a youth, aged 18 years, with a peculiar Skin Disease of three years duration, exhibiting more or less symmetrically disposed patches of violet colour on the shoulders, on the back, and on the front of the thighs It was thought to be a mild type of scleroderma.—Mr P H Gardner showed a girl, aged 13 years, whose Diseased Hip-joint he had curetted and then injected with iodoform emulsion last August She was now apparently quite cured.—Mr Gardner also showed a boy upon whom he had satisfactorily performed Bassini s operation for the Radical Cure of Inguinal Hernia.—Dr T Horton showed a boy with Genu Valgum. A skiagram apparently showed that an abnormality about the head of the tibia was the chief cause, but an operation rectifying this was followed by no improvement. Macewen s operation on the femur was then performed with an excellent result.—Dr Horton also showed a girl with a Spontaneous Arterio-Venous Aneurysm between the dorsalis pedis artery and the internal saphenous vein.—Mr Rupert Wheatley read a paper on the Dental Aspect of a Few General Diseases in which he called attention to the general neglect of the state of the mouth and teeth with all their septic organisms during the course of general diseases. Alluding to the proved virulence of some specific microbes in the presence of other different organisms he suggested that the occasional malignancy of some general diseases was due to their association with other septic organisms derived from the mouth.—Most of the members present took part in the discussion.

WATER-SUPPLY OF BATH.—A public meeting was held in Bath on Dec 20th under the presidency of the Mayor to consider the proposals of the corporation to promote a Bill in Parliament to enable it to carry out works to increase the water supply of the city at an estimated expenditure of £44,000

DEPARTMENTAL COMMITTEE ON THE NURSING OF THE SICK POOR IN WORKHOUSES —The committee of the Workhouse Infirmary Nursing Association has drawn up a memorial to the President of the Local Government Board, protesting against the proposed creation of 'qualified nurses —viz women trained for one year in a small workhouse and holding a certificate of good conduct and proficiency from the superintendent nurse, the chairman of board of guardians, and medical officer

Reviews and Notices of Books.

A Manual of Medicine Edited by W H. ALLCHIN, M D, F R C P Lond, F R S Edin., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital Vol. IV Diseases of the Respiratory and of the Circulatory Systems. London Macmillan and Co, Limited 1902. Pp 493. Price 7*s* 6*d*

THIS volume commences with a chapter on the General Anatomy and Physiology of the Respiratory System by Dr Leonard Hill, F R S, lecturer on physiology at the London Hospital Medical College Dr Hill's remarks will be found very instructive, especially those dealing with the mechanism of respiration The Diseases of the Upper Respiratory Tract are described by Dr Lewis A. Smith physician to the Poplar Hospital. A good clinical account is given of adenoids, but with regard to the treatment of this affection we are not entirely in accord with the writer He says "The treatment of adenoids consists in their removal." If we understand him correctly we consider that he is too sweeping in this statement Surely the question of operation is dependent upon the quantity of adenoid growth present. If small in amount atrophy may well be hoped for and operative procedures may for a time, at any rate be postponed. In describing the method of operation Dr Smith advises a general anæsthetic but states that the operation is quite possible under cocaine and adds "Some authorities use no anæsthetic, either local or general" This last procedure he quite disapproves of, we should go further and condemn the application of cocaine alone Dr Hector W G Mackenzie, physician to St Thomas's Hospital and to the Hospital for Consumption, Brompton, writes on Diseases of the Lower Respiratory Tract. The article as a whole is excellent but in our opinion its value is impaired by the general arrangement which has been adopted. A large number of diseases are described but instead of considering each disease in full, as is the plan followed in most text-books—that is to say, discussing the etiology, pathology, morbid anatomy, symptoms, prognosis diagnosis, and treatment under the heading of one particular disease—preliminary sections have been written on general etiology morbid anatomy and pathology, and general symptomatology We do not consider this plan a convenient or praiseworthy one. For purposes of reference it is most cumbersome and we doubt whether it will be found of value to students. The information contained in Dr Mackenzie s contribution is ample and accurate but it is a retrograde step to separate etiology and pathology so completely from the clinical description. The section on Diseases of the Pleura is by Dr F de Havilland Hall, physician to the Westminster Hospital, whilst Dr Allchin describes the Disorders of the Diaphragm.

The Physiological Introduction to the Vascular System is by Dr Leonard Hill and we can speak in terms of the highest approbation of this section of the book. The first principles of the circulation are described in a manner which rivets the attention and cannot fail to instruct. The physiology of the component parts of the vascular system is considered in such a manner as to convey the maximum amount of information in the space allotted to the writer We can cordially recommend a careful study of these pages to students about to commence their clinical work. The section on Diseases of the Circulatory System is by Dr J Mitchell Bruce. His remarks on the general etiology and morbid anatomy and pathology of diseases of the heart are excellent. The general symptomatology of these diseases is graphically described and a clear idea is conveyed to the reader of the different phenomena which may be encountered in dealing with cardiac affections. One

&c. He next referred to the successive phenomena seen when an electric discharge was taking place in a Crookes's tube which was being exhausted. The kathode rays were due to streams of electrified particles emitted from the kathode at a high velocity They could be deflected by a magnet, they excited fluorescence, cast shadows of interposed objects, rendered platinum foil red hot when focussed upon it, and by the bombardment of the anti kathode they set up quivers in the ether which were propagated in all directions and which constituted the Roentgen rays. These rays possessed all the properties of the ultra violet rays enumerated above but could not, like them, be reflected, refracted, or polarised, nor could they be deflected by a magnet like the kathode rays. Roentgen considered that his rays were longitudinal waves in the ether, others had held that they were transverse waves of very small wave length, their failure to be refracted being due to their being unhindered by the molecules of ether in much the same way that a mouse might pass through a thicket which would delay a man. Mr Tomlinson finally alluded to Becquerel's discoveries and described the new elements polonium, radium, &c., which had the power of spontaneously emitting Roentgen and kathode rays —The proceedings terminated with a cordial vote of thanks to Mr Startin, Mr Tomlinson, and Mr Wigmore.

HARVEIAN SOCIETY OF LONDON —A meeting of this society was held on Dec. 18th, Mr W Watson Cheyne, C B, F R.S, the President, being in the chair — Dr A. Morison exhibited a child, five months old, who showed the Dilated Veins which a French writer described as "venous dystrophy" and attributed to specific disease Dr Morison could find no evidence of specific disease in the case which he exhibited and he ascribed the malnutrition of the child and the increased intracranial pressure to over production of children by a delicate mother rather than to specific disease.—Dr Wilfred J Harris showed a woman, aged 24 years, who suffered from a Sore throat, not diagnosed as diphtheria at the time (January, 1901) A few weeks later she had difficulty in swallowing and nasal regurgitation with altered voice The muscles of the lips and eyes afterwards became affected. In November she was treated by hypodermic injections of strychnine but she became worse. There were at the present time complete paralysis for reflex and voluntary movement of the palate, bilateral wasting, and almost complete paralysis of the orbiculares palpebrarum, less marked in the orbicularis oris The tongue was partially atrophied and weak. Sensations in the pharynx were diminished The deep reflexes were all brisk but the plantar reflexes could not be obtained. Electrical reaction was very slight to strong faradism in the soft palate with well marked reaction to galvanism, K.C C being greater than A.C C There was very slight reaction to faradism in the orbiculares palpebrarum with better marked reaction to galvanism, K.C C being greater than A.C C Under treatment with galvanism of the affected muscles for five months and with iodide of potassium in from 10 grain to 15-grain doses three times a day the condition had scarcely altered —Dr J S Risien Russell showed a case of Peripheral Neuritis with paralysis of the right side of the face of peripheral type, paralysis of the right external rectus, slight paresis of the left external rectus, and well marked optic neuritis subsiding into atrophy Under treatment the paralysis of the face and of the external recti had disappeared and the limbs were also improving, though the patient was still unable to stand or to walk No cause had been determined but the appearance of the patient and the features of the paralysis of the limbs made alcohol most probable.—Dr E Cautley showed for Mr P L. Daniel a woman, aged 63 years, on whom Resection of the Supra-orbital Nerve had been performed for severe neuralgia The pain followed a bad attack of herpes in the region supplied by this nerve and was accompanied by marked trophic changes in the skin and hair affecting also the blood vessels Medical treatment proved useless The operation had done no marked good to the pain, but the nutrition of the affected parts had somewhat improved.—Mr F Jaffrey said that he had seen marked improvement in certain cases of severe trigeminal neuralgia by the injection of osmic acid into the affected nerve In a case under his own care where the third division of the fifth nerve was affected, he trephined the ramus of the lower jaw and injected osmic acid into the inferior dental and gustatory nerves with complete success —The cases were also discussed by Mr Campbell Williams and Dr G A. H Barton

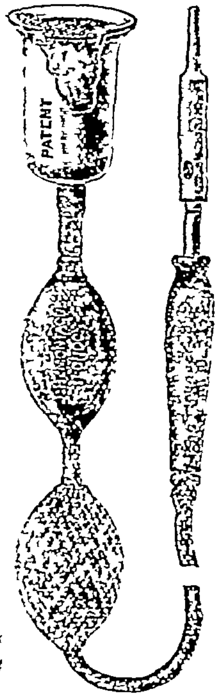
ÆSCULAPIAN SOCIETY —A meeting of this society was held on Dec. 19th, Dr Thomas G Stevens, the President, being in the chair —Mr Reginald Brown showed a man, aged 33 years, whose Ulna was broken two years ago and though treated in various ways was unhealed He cut down upon the fracture and scraped away the fibrous union, placing the arm and forearm on a splint Healing resulted in six weeks —Mr F Hewitt Oliver showed a radiogram of an Ununited Fracture at the outer inch of the clavicle in a woman, aged 55 years, who suffered but little inconvenience from the non union —Dr Arthur T Davies showed a specimen of an Aneurysm of the whole Aortic Arch from a man, aged 52 years He died from hæmorrhage into the left bronchus following a slight cough that ruptured the aneurysm. Dr Davies remarked on the rarity of rupture into the left bronchus —Dr Lewis A. Smith read a paper entitled "Errors I have Made and Seen" In it he said that gonorrhœal rheumatism was often mistaken for acute rheumatism. Gonorrhœal rheumatism affected the peri articular tissues and acute rheumatism the articular tissues Pain referred to the left scapula in a man, aged 34 years, was thought to be rheumatism but four months later was proved post mortem to be due to an aneurysm. Any fixed pain should give one pause before labelling it as rheumatic Typhoid fever might resemble other diseases besides typhus fever and thus collections of pus that were hidden, miliary tuberculosis, and appendicitis were often mistaken for typhoid fever Glycosuria was not synonymous with diabetes, for it might be transient, resulting from overstrain of mind or faulty digestion Yet he believed that the simplest occasional passage of sugar in the urine was at the lowest end of the diabetic scale at the other end of which was the most acute wasting with polyuria, acetonuria, and coma. Confusion might arise readily if a patient's statement unproved were accepted when vomiting was reported, for a mere regurgitation might be called vomiting Vomiting as a symptom in tabes dorsalis must be kept in mind, as also must repeated small doses of an irritant poison Acute abdominal pain was not due always to abdominal disease but might be reflected from the thorax, as in pleurisy and pneumonia. A young man who was anæmic, had been constipated for four days, and had vomited and suffered severe abdominal pain, was prepared for laparotomy when he was noticed to have a sulphide line due to lead and so his abdomen was not opened A man, aged 34 years, who had severe, sudden abdominal pain that did not lessen and whose pulse was worse in a few hours, was operated upon and was found to have hæmorrhage into the pancreas. He died in 24 hours and it was found that the blood vessels to and from the pancreas were thrombosed Empyema was often overlooked and should not be, for in any doubtful case of one sided chest dulness an exploratory needle should be inserted Dr Smith said that all their mistakes taught them to have more care and always to make a post-mortem examination

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY —A meeting of this society was held on Dec. 17th, Dr E Symes Thompson (London) the President, being in the chair —Dr Percy G Lewis (Folkestone) read a paper entitled "Convalescence and Chronic Illness," of which the following is a summary The symptoms of convalescence were those of lowered vitality The system suffered from granular degeneration of the different organs affecting their functions, hence deficient elimination and auto-intoxication. Specially noteworthy was the effect of acute illness on the heart Most convalescents were found to have dilated hearts which required appropriate treatment. Chronic invalids also suffered from auto-intoxication. It was important that a convalescent should be as carefully watched as an acute case. In treatment change of air to the nearest seaside health resort was advisable as soon as possible. This was of use not only by helping the patient to resume the habits of health and to cast off those of illness but the pure stimulating sea air with the influence of sunlight had a remarkable effect in restoring healthy metabolism and aiding repair Graduated medical exercises with heart tonics and careful attention to diet were recommended.—The paper was discussed by Dr J Groves (Carisbrooke), Dr W V Snow (Bournemouth) Dr Harry Campbell (London), Dr C Begg (Bath), Dr T F portrait of the late Dr David Little Among the editorial paragraphs is one calling attention to the fact that Sir Dyce Duckworth s recent introductory address has been printed and bound in covers resembling those of twopenny notebooks and suggests the possibility of students reading novels bound in similar covers during the course of a lecture This reminds us that some years ago a correspondent wrote a letter to the press complaining that he had seen a young lady in a second class railway carriage reading a copy of one of Zola's most realistic books bound in a cover entitled "De Imitatione Christi," and we ourselves have seen a copy of the ' Kreutzer Sonata " bound up under the title of "English Spelling as it is." The Christmas number of this *Gazette*, which for the most part is devoted to matter of a light nature, is an excellent one

New Inventions.

A SAFER METHOD OF PROVIDING VAPOUR FOR HEATING PAQUELIN S CAUTERY

THE ordinary method of obtaining vapour for heating Paquelin s cautery—by forcing air through benzoline contained in a glass bottle which is attached to the clothing of the operator and often in close proximity to fire—is not, even under the most favourable condition entirely free from the risks of accident from violent explosion. In order to eliminate the risks of explosion while using Paquelin s cautery and to facilitate the heating of it I have had a particular *form of open* metal evaporating apparatus constructed for attachment to the hollow cautery handle in the place of the customary closed glass bottle With this new arrangement the vapour employed for increasing and maintaining the glow of the cautery is obtained not by driving air through a mobile liquid confined in a closed glass bottle but by drawing air through an open metal container filled with cotton wick moistened with benzoline intended for evaporation The mixture of air and inflammable vapour thus formed is driven by the force of a ball bellows into the platinum point. The metal container in which the wick is placed (lengthwise) communicates above with the inlet of the bellows, but below is open to the air, the lower opening however is protected by a wire gauze screen. This screen has two functions the first to retain the cotton wick in place, the second and more important, to protect the inflammable fluid and vapour present in the container from ignition by fire. To charge the apparatus a few drops of benzoline (say half a drachm or more according to requirement) are poured through the wire gauze screen on to the wick, in doing so the liquid should be poured evenly over the whole of the exposed surface of the wick. When heating the cautery the terminal should be heated to a dull red glow in the flame of a spirit lamp before the vapour is driven into it otherwise the vapour will fail to ignite within the terminal but will ignite at the vent holes, should this occur it is merely necessary to cease pumping until the error has been corrected There is not the least danger of the apparatus exploding, it may even be passed through the flame of a spirit lamp with safety The vapour is protected from ignition below by the presence of the wire gauze screen, above by the valves that intervene between the container and the cautery



I am indebted to Mr J H. Montague of 101 New Bond street, London, W for the manufacture of this little apparatus

ANALYSIS OF FOREIGN MEDICAL JOURNALS

Beobachtung einer Entzundung des linken Ohres durch mehrere maden veranlasst, deren vollstandige Verwandlung nach ihrem Abgange gelang, Von Dr Kuntzmann

A case of Inflammation of the left Ear, occasioned by the presence of several larvæ in the external meatus

A Surgeon of Berlin Mr MOHR was consulted some time since, by a little boy of six years of age, who had been suffering for five days a very severe pain in the left ear, without intermission and which pain was daily increasing in intensity On examination of the parts he found that the proper auricle was sound but that the external auditory passage was very much swollen, and from it pus mixed with blood was discharged In other respects the child appeared to be well. Mr Mohr ordered an infusion of chamomile, with honey of roses and tincture of myrrh, to be injected into the ear, and an emollient poultice to be afterwards applied The next day when injecting the ear, Mr Mohr was very much surprised to see several moving bodies, and with a small forceps he drew out six worms of the same size and figure. Soon afterwards the pains ceased, and in a few days the patient was quite well, without having any deafness or other inconvenience.

Each worm or *larva*, was rather more than half an inch long, and one twelfth of an inch in breadth, of a yellowish white colour, and composed of many soft circular portions locking the one into the other On the head of each were two brown crooked projections, bent downwards, between which was found a little conical figure called, by Reaumur *dard* This dard was not straight as it is in the domestic fly but curved backwards the same as the little horns, although less so

Mr Mohr gave two of these larvæ to Dr Kuntzmann and he placed them in a little box containing some finely powdered dry earth, a small piece of meat, and a little dung they would not touch either of the two last substances, but plunged themselves immediately into the earth Two days after he found them both changed into perfect chrysalides These were brown in colour, cylindrical in figure thin, and obtuse at each end, immovable and apparently composed of many rings In about five days they became perfect insects with wings spotted with grey and black and Professor Illiger, when they were shown to him, said that they belonged to the genus *Tachina*, but that they formed a new species of that genus

This boy had been frequently in the habit of sleeping in the open air in a wood near his home, and there can be no doubt but that the eggs from which these larvæ are produced were deposited in his ear by an insect while he was asleep.—*Journal der Practischen Heilkunde, August*

LEICESTER MEDICAL UNION AND VACCINATION —The memorial to the President of the Local Government Board which follows has been sent by the Leicester Medical Union and this body hopes 'that any other medical societies who agree with it will forward similar ones '

[COPY]

To the Right Honourable Walter Long M.P President of the Local Government Board this memorial of medical practitioners constituting the Leicester Medical Union respectfully sheweth —

That in the opinion of your memorialists it would conduce to the practice of vaccination in this country if Parliament were to enact that every duly qualified medical practitioner shall be put on the same footing in regard to the practice of vaccination as that on which public vaccinators now are

It is well known to your memorialists that many adult persons who refuse to visit the public vaccinator would have their children vaccinated and would be themselves revaccinated if this could be done free of cost to themselves by their regular medical attendant

(Signed for the Leicester Medical Union)
O F BRYAN President
JAMES PEACOCK, Honorary Secretary
335 Humberstone-road Leicester Dec. 20th 1902.

of the best sections is that headed, General Course and Prognosis of Heart Disease It is more especially this aspect of disorders of the heart that the student finds difficult to understand From the point of view of his future professional life it is, of course, of the utmost importance that he should fully comprehend the various details which have to be taken into consideration when forming a prognosis in any given case Dr Bruce's remarks will be found most valuable as an aid in this direction. We may further draw attention to the observations on cardiac failure, which are well worthy of note The section entitled "The Principles of Treatment in Disease of the Heart" should also be carefully studied. The many suggestions found in the pages devoted to this branch of the subject will be found useful to students and to practitioners alike.

The volume ends with an excellent article on Œdema by Dr Allchin The pathology of the condition is well described and its clinical aspect is considered at length.

LIBRARY TABLE

Executors a Summary of their Powers, Duties, and Liabilities, together with an Epitome of the Death Duties By H P C KELLAND, Chartered Accountant Second edition Published by the author at 53, Victoria street, Westminster —The duties of an executor cannot be too clearly understood by those who are called upon to discharge them In practice executors are almost always advised by a solicitor as to the course that they should pursue, but for many reasons a man may wish to know without taking legal advice what his powers and liabilities as an executor are He may, for instance, want to make up his mind whether he will accept office or not and may prefer to do so without the formality that is implied in seeking legal advice In such and similar circumstances Mr Kelland's little book will be found to contain all the necessary information put in a very clear and concise form Similarly, the epitome of the death duties, legacy duties, and succession duties, which makes up the latter half of this pamphlet, is very comprehensible and brief. Medical men are not always good men of business, so that it is not unlikely that some of them may find Mr Kelland's pamphlet to be of great practical use

Whitaker s Almanack, 1903 London 12, Warwick lane, Paternoster row —We have at length found something in the incomparable "Whitaker" at which to grumble, and that is the new perpetual calendar published in this year s issue. Somehow it does not seem to us so convenient for reference as the one published in last year's issue, but that may simply be because we have not yet got accustomed to it It is, we think, a matter for congratulation that "Whitaker" should not be always at the apex of perfection or we fear that he would meet with the fate of Aristides and be ostracised, because people were tired of hearing his praises sung In all other respects the almanack is as admirable and indispensable as usual.

Whitaker s Peerage 1903 London J Whitaker and Sons, Limited —This valuable work is not only a peerage but a baronetage, knightage, a list of companions of orders of Privy Councillors, and of bishops both spiritual peers and others The introduction is full of interesting matter and the amount of information in the volume is marvellous So is the manner in which the details are kept up to date.

"*Who s Who" for 1903* London A. and C Black. Price 5s net.—"Who s Who" for this year is almost entirely biographical, all the tables which appeared in former issues having been omitted with the exception of a list of the Royal family and a small obituary list. The publishers, however, state that it is hoped to issue separately the tables which have appeared in former issues. As to the biographies, while some are interesting others are not, and the want of proportion in their length is very noticeable. But the book as a whole is enormously useful, as every working journalist knows, and the amount of trouble expended in its production must be very great.

The Englishwoman's Year Book for 1903 London A. and C Black. Price 2s 6d. net —This useful volume contains a mass of information as to women's employment and the work which they do in literature, education, temperance, social reform, the religious orders, and sundry other spheres. There is a full summary of laws as affecting women and children which will be found to be serviceable.

HOSPITAL MAGAZINES

St Bartholomew's Hospital Journal for November contains the concluding part of Mr D Arcy Power's paper on the Elizabethan Revival of Surgery *Apropos* of the retirement of Sir William S Church, Bart, K.C B, senior physician to St Bartholomew's Hospital, there is an interesting sketch of the life of the President of the Royal College of Physicians of London in his connexion with the institution at West Smithfield and there is another instalment of Smithfield Letters collected by "John Street Road." "Four Generations of Ophthalmic Surgeons to the Hospital" is the title of a not very well reproduced photographic group of Mr Henry Power, the late Mr Bowater Vernon, Mr Walter H. H Jessop, and Mr W T Holmes Spicer

Charing Cross Hospital Gazette for December describes a visit to the hospital clinics at Bonn. The writer says that "a month's grind at Hugo s System and three five-pound notes will carry one along for four weeks very comfortably" Mr C Carter Braine gives an account of the anæsthetic registers of the hospital from 1895 to 1900

St George's Hospital Gazette for November opens with a very interesting and instructive little note entitled "A Breath of Ozone," dealing chiefly with baths and bathing, by Dr Robert Barnes In it he incidentally mentions that his first contribution to medical literature was a case of Severe Vomiting after Immersion in a Tartar Emetic Bath published in THE LANCET in 1839 Among other interesting matter in this number is the report of a lecture by Dr H A. Des Vœux on the Treatment of Disease by Exercises, Active and Passive.

Guy's Hospital Gazette of Dec 20th is a very good number and the pencil of the caricaturist has been busy An excellent reproduction of the illuminated "Arms Crest, Supporters, and Motto belonging to the Hospital in the Parish of St. Thomas's in Southwark founded by Thomas Guy" and signed by "John Anstis, Garter," forms a supplement to this issue which also contains a copy of the original grant in the counting house of Guy's Hospital

St Mary s Hospital Gazette for December publishes a very interesting account of Life in a Pioneer Town of West Australia by Mr Graham Blick. "The Leucocyte s Lament," which is described as a physiological ballad by Augustus O'Leary, is amusing

St Thomas s Hospital Gazette for December contains the concluding portion of Dr W S Colman's paper on Three Distinguished Amateur Physicians which is well worth reading Naturalists will appreciate a paper on Egg Collecting

University College Gazette for December chiefly devotes its pages to college notes, meetings of college societies, and such like matters It contains a brief memoir of Dr J H. Gladstone—"a link with a former generation of professors and students."

The *Manchester Medical Students' Gazette* for December reproduces as a supplement to the *Gazette* a very good

FREYBERGER as a pathologist to be employed by coroners in the County of London for the making of post mortem examinations Dr FREYBERGER has been consequently employed to make such examinations and to give evidence at inquests, particularly by Mr TROUTBECK, the recently appointed coroner for South-West London In the interests of the public and of the medical profession alike there are in our opinion many reasons which render the innovation described undesirable, but we propose for the present to postpone the discussion of these and to examine the legal aspect of the question only, to which attention was particularly called at the recent meeting of the South-West London Medical Society Our report of this meeting which will be found on page 126, sets out the opinion of Mr MUIR MACKENZIE, obtained at the instance of the society Our own views were formed some time ago, but the publication of them was delayed in order that the development of the question might be watched and that, if possible, the precise legal positions adopted by the London County Council and by Mr TROUTBECK might be ascertained. These we do not find easy to determine, although we readily concede that both the Council and the coroner are acting in good faith and under the impression (in our view a mistaken one) that the course adopted is for the public good The position of the Council may, however become clearer when that body replies to the South West London Medical Society

As matters stand at present, the chairman of the Public Control Committee of the County Council has made a statement on the subject which has been published in THE LANCET[1] to the effect that the Council has been for some time dissatisfied with the existing law as to the making of post-mortem examinations and has in vain urged successive Governments to alter it. In these circumstances, he says, the Public Control Committee "considered in what way improvement could be made by the Council under the existing law and on July 1st last they reported to the Council the result. They recommended amongst other reforms 'That all coroners be informed that in the opinion of the Council it is desirable that post-mortem examinations in inquest cases of a special nature should be intrusted to a specially skilled pathologist And the Council approved this recommendation On the same day Mr TROUTBECK was appointed coroner for the south western district and he agreed to give effect to the Council s resolution." The statement from which we have quoted further informs us that Dr FREYBERGER was found to be an experienced pathologist and was also prepared to make the post-mortem examinations and give evidence in cases requiring special pathological experience and skill for the statutory fee of two guineas," and that it was accordingly "suggested" that he should be employed in special cases, but not so as to supersede the medical attendant on the deceased in ordinary cases. We do not propose to discuss at present whether in point of fact Dr FREYBERGER has only been employed in cases of special difficulty, but on the general question of the arrangements made with regard to him we would point out that the statement referred to admits that the law with which the Council was dissatisfied remains unaltered, and speaks of a resolution with a view to an improvement "under the existing law," without attempting to show that the existing law justifies or permits the "improvement" It will be observed, however, that Dr FREYBERGER is to be paid the statutory fee and that it is therefore apparently admitted that unless his employment is justified by statute the fees paid to him have not been properly paid.

Mr TROUTBECK in the course of an inquest held on Dec. 22nd, 1902, made some observations upon the adverse criticism which his employment of Dr FREYBERGER had evoked, making references to the Coroners Act of 1887 and to arrangements made by the County Council with Dr FREYBERGER. He, however, like the chairman of the Public Control Committee, did not make clear the source of the power under which the County Council made its arrangement with Dr FREYBERGER and its "agreement" with himself. He appeared to regard the choice of a medical man to make a post-mortem examination or to give evidence at an inquest as a matter wholly within the coroner s discretion, but we are not informed that he has at any time quoted any authority for this proposition. The calling of medical witnesses and the holding of post mortem examinations are governed by Section 21 of the Coroners Act, 1887 (50 & 51 Vict, c. 71), the gist of which is sufficiently given in Mr MUIR MACKENZIE s opinion. We quote in full the third subsection only, because it defines the conditions under which special medical evidence is to be obtained. Section 21, Subsection (3), is as follows —

> If a majority of the jury sitting at an inquest are of opinion that the cause of death has not been satisfactorily explained by the evidence of the medical practitioner or other witnesses brought before them, they may require the coroner in writing to summon as a witness some other legally qualified medical practitioner named by them, and further to direct a post-mortem examination of the deceased, with or without an analysis of the contents of the stomach or intestines, to be made by such last-mentioned practitioner, and that whether such examination has been previously made or not, and the coroner shall comply with such requisition, and in default shall be guilty of a misdemeanour

It will be seen that this subsection, at all events, does not provide for the selection of a pathologist by any public body such as a county council or for the employment of any such person to make post-mortem examinations by the coroner upon his own initiative In the event of the jury being dissatisfied with the evidence of the local practitioner, called under the two preceding subsections, they are to require the coroner to obtain other expert evidence, the selection of the person to give it resting with the jury although, no doubt, the coroner's guiding influence would properly make itself felt upon such an occasion. The 22nd section of the Act provides for the fees of medical witnesses summoned to give evidence "under this Act," and we do not know of any power to pay fees to any medical witnesses not so summoned. This points to a possible remedy for those aggrieved which apparently was not suggested to Mr MUIR MACKENZIE but which seems to have been successfully adopted in the case to which we are about to refer

We are not aware of any difficulty having before arisen in England that could call forth a legal decision upon the matter under discussion, but a similar attempt to introduce a general medical referee for the purpose of inquests was

THE LANCET.

LONDON SATURDAY JANUARY 10, 1903

The Imperial Vaccination League

IN the absence of organisation there can be no guarantee of victory and the apathy of human nature renders such organisation necessary in order that the truth may be made known and its teachings brought home to those whose duty it is to modify the laws in accordance with the demands of science In the matter of vaccination there is a crisis approaching At the end of the current year the provisions of the Vaccination Act of 1898 must be ended, extended, or mended, and it is of the greatest importance to the public health, in so far as its freedom from small-pox is concerned, that such provisions shall be amplified and improved We discussed in a recent leading article the question as to who should administer the coming Vaccination Act [1] and we see no reason materially to modify the position which we then took up—i e, that of the several bodies more or less concerned, the Local Government Board, the guardians, and the district or county councils, the last-named bodies are best fitted to undertake the administration of vaccination. Among the reasons which we adduced for this view were the facts (1) that county councils are least likely to be influenced by the small section of well meaning enthusiasts to be found in every community, and (2) that county councils would be able, either alone or in combination, to erect laboratories which in the first instance would serve for the preparation of calf lymph, but which might afterwards be so expanded as to provide for general bacteriological and chemical examinations for the county Thirdly, we pointed out that the county councils in their capacity of education authorities would possess great facilities for administering the Act. County councils were created in 1888 by a Government of the same political views as that which is now in power, and it would be a graceful act on the part of the Government, showing its appreciation of the work done by certain county councils in furthering the public health, if the proposed powers were conferred upon them We have also urged from time to time the necessity for placing revaccination upon the same basis as primary vaccination—i e., that such revaccination shall be compulsory at school ages in the same sense, and with the same loopholes for what is called 'conscience," as primary vaccination There is, too, need, as we have for many years insisted, to render "one mark" vaccination a thing of the past and to make it impossible for a practitioner who degrades his profession by advertising "one child, one mark, one shilling" to pursue his calling This point and many others equally important are made by Dr DUKES in the able letter upon the present position of vaccination which we publish this week.

Now, the Imperial Vaccination League, which is presided over by the Duke of FIFE, and which contains in the list of its vice presidents an array of names which from the point of view of academic distinction it would be difficult to beat, has for its programme a scheme very similar to the one that we have sketched. The object of the League is also to assist in the education of the people in the matter of vaccination and particularly, we may add, revaccination. The League has our entire sympathy and we should be glad to see it so supported financially by those who agree with its aims as to enable it to provide legal assistance in cases in which baseless allegations are made against vaccination, allegations which are generally supported by legal assistance from a society of very different calibre to the Imperial Vaccination League. If those who appreciate the value of vaccination were possessed of a tithe of the energy of those who fail to appreciate it there would be but few "consciences" left for our magistrates to deal with. A deputation from the Imperial Vaccination League is to wait upon the President of the Local Government Board during the coming week and we have no doubt that the *influence and ability which the members of the League* possess will enable the deputation to put its case before Mr LONG with such clearness and force as to carry conviction. It is, however, to be hoped that the deputation will be *content to advocate certain principles and to leave* the application thereof to the Cabinet Minister who acts to some extent as Minister of Public Health. These principles should, we think, embrace the following points (*a*) the removal of vaccination administration from boards of guardians, (*b*) the enforcement of revaccination in the same sense as primary vaccination is now enforced, (*c*) the definition of "efficient" vaccination, and (*d*) the provision of laboratories under the general supervision of the Local Government Board in which supplies of calf lymph should be prepared We feel that if the League contents itself with enforcing these principles it will be doing a greater service, and one which is more consistent with its aims and constitution, than if it raises a discussion as to whether county or district councils shall administer the coming Act

But the League must state its case emphatically and should point out to Mr LONG that if he, as the protector of the public health, wishes practically to eliminate small pox he must follow the example of the German Empire which has so eliminated the disease Let the League be no consenting party to apologetic measures. And let it not be forgotten that the protection of the *public health* is not a political question it is an elementary duty incumbent upon both parties. We trust, therefore, that the League, having put its case before Mr LONG, will also put it before those who sit on the opposite side of the House seeing that their attitude will decide whether the coming Bill is to be regarded as a non-contentious measure or is to be made an excuse for the exhibition of party bias

◆

The Medical Man, the Coroner, and the Pathologist

UNDER the above heading reference has recently been made in THE LANCET upon several occasions to the selection or indication by the London County Council of Dr LUDWIG

---

[1] THE LANCET Oct 25th 1902 p 1138.

Annotations.

'Ne quid nimis."

THE LANCET RELIEF FUND

THE annual report of the Almoners of this Fund will be found on page 124 In the case of an institution such as THE LANCET Relief Fund founded for well-defined objects, the history of the past will form largely the experience of the future, and a retrospect of the incidents of the year's work just concluded reveals no new features The majority of the cases brought to the notice of the Almoners are still those of the widow and orphans suddenly plunged into grief and distress by the loss of the husband and father upon whose existence their own practically depended. The details of these cases plainly reveal the struggle to make both ends meet which prevailed whilst the bread winner was yet alive. It is not easy to picture a more distressing position than that of a mother of a family who, as she turns away from the death bed of her husband, almost before she has realised the severity of her own personal loss, is compelled to contemplate the worldly side of that loss as she finds that the entire support of herself and of her children is gone During the past year 73 applications for assistance were received. Of these, 24 were relieved by gifts of money ranging from £5 to £30 which involved the expenditure of £318 Many letters from those who have benefited have again been received expressing gratitude for the prompt relief which has enabled them to bear, and oftentimes to overcome, their difficulties To those who have so ungrudgingly helped us in carrying out the work of the Fund it is again our privilege to make public acknowledgment of our indebtedness—to Sir William Selby Church, Bart K.C.B., the President of the Royal College of Physicians of London, to Sir Henry Greenway Howse, the President of the Royal College of Surgeons of England (to whom, as one of our Almoners, we offer our congratulations on the distinction of knighthood conferred upon him by His Majesty the King), to Sir William Turner, K.C.B., the President of the General Medical Council, and to the veteran Sir Henry Pitman, for many years the registrar of the Royal College of Physicians of London The application form of THE LANCET Relief Fund will be found in our present issue and can be readily detached for use in case of need. We again take an opportunity of asking those of our readers who may have occasion to assist in furthering any application made for relief to note carefully the conditions which entitle applicants to participate in the benefits of the Fund, as it is still found that many requests are made in behalf of cases outside the scope of its working All applications should be made on the prescribed form and should be sent to the Secretary of THE LANCET Relief Fund, THE LANCET Offices, 423, Strand, London, W C

THE NECESSITY FOR AMENDMENT OF THE REGISTRATION ACTS

IT is an indubitable fact that our very loose system of registration of deaths opens the door to both crime and fraud. The latest example of this which has come under our notice was the cause of an inquest held by Mr S Brighouse, who is one of the county coroners for Lancashire, concerning the death of a child, aged two months, named James Gallagher The coroner in opening the case related the following remarkable story The child was born on Oct. 9th and was attended for illness by Mr W Hamilton of Wigan. He last saw the child on Dec. 10th and on Dec. 12th the mother told Mr Hamilton that the child had died that day Mr Hamilton therefore gave her the certificate On Dec 13th the mother registered the death and obtained a club paper by which she would be able to draw £2 for funeral expenses The registrar handed over the burial certificate which the woman promptly lost Curiously enough, it was found the same evening by the manager of a firm of undertakers, Mr Johnson He called that same night at the address given and found that the child was still alive. The mother demanded the certificate back but Mr Johnson refused to part with it and handed it over to the police. On Dec. 13th the mother again went to the registrar and said that she had made a mistake and that the child had died at 2 A M that morning The registrar told her to get another medical certificate On the 15th the representative of the undertaking firm called again and found the mother washing the child who was still alive. On the 18th the mother appeared at the registrar's office with another certificate and the registrar promptly forwarded the whole story to the police who communicated with the coroner who ordered an inquest and a post-mortem examination. The mother, who gave evidence, said that she quite thought that the child was dead when she went for the first certificate. Mr Hamilton, who had attended the child, said that he gave the certificate on the mother's statement because from what he had seen of the child he had every reason to anticipate his death. He had made a post-mortem examination and had found the cause of death to be pneumonia. The jury returned a verdict of "Death from natural causes." As we understand that proceedings may be taken against the mother we are thereby precluded from commenting upon her conduct, but it is obvious from the facts which we have recounted that it should be made obligatory for any medical man before giving a death certificate to satisfy himself of the fact of death For such certificates a fee should be made legally payable.

SILLY ADVICE

JUST recently a great deal has been heard from the clergy as to their objections to having lay managers set over them to decide as to what they shall or shall not teach This being so it is somewhat remarkable to find a parish priest going out of his way to advise unorthodox treatment in the case of illness. We have upon various occasions animadverted upon the conduct of religious houses which sell some elixir or salve warranted to cure all and sundry diseases, we have also rebuked various clergy of the English Church for issuing circulars prescribing three drops of carbolic acid as a cure for 'fever" or for undertaking medical treatment in other forms Such persons, however, though foolish, were of no influence outside their proper spheres and therefore not of much importance But from a correspondence which we have had forwarded to us we are sorry to have to put on record a grave dereliction of duty on the part of a metropolitan parish priest who is by no means a fool, who is on the contrary a brilliant writer, an able preacher, and who has given up most of the good things of this world in pursuit of his calling It appears that a supporter of the Rev Mr —— is afflicted with some incurable disease of the œsophagus. The Rev Mr —— thereupon wrote to his supporter and said, "I wish you would try Mr Simms, 36 High street, Oxford, for your trouble you have which prevents you from swallowing He has some wonderful stuff which has an effect in dispersing 'growths' of many kinds. I really think that it would be worth trying" The sufferer accordingly, at the earnest request of his wife, wrote to Mr Simms and received an made at Dublin in 1877 and was held to be illegal under the provisions of the Coroners Act (Ireland), 1846,[2] a statute which regulates the calling of medical witnesses at inquests upon lines generally resembling the provisions of the English Act. In this instance the corporation of the county of Dublin had agreed to pay a fixed yearly salary in lieu of fees to a medical practitioner *permanently appointed by the coroner to attend as a medical* witness at all inquests to be held in the city of Dublin. The question was raised by a ratepayer who moved to prevent the public auditor from passing payments so made and the court in giving judgment intimated that the appointment of a permanent medical witness was illegal and that medical witnesses should be appointed from time to time as circumstances might require.[3] A perusal of the report of this case will, to those who have access to it, suggest the consideration of a further question which will have occurred to some already. The chairman of the Public Control Committee in a passage which we have quoted has said that Mr. TROUTBECK "agreed" to give effect to the County Council's resolution. We would ask for a more definite statement upon the subject of this "agreement" either from the County Council or from Mr. TROUTBECK. We should hesitate to infer that a coroner about to occupy a judicial position of some importance bargained with the body appointing him as to the manner in which he would carry out duties already defined for him by law. We should certainly question the propriety of any promise ostensibly binding anyone filling such an office to summon a particular witness before him to the exclusion of those who might otherwise be called, more especially should such a promise involve the payment of fees to the nominee of a body holding the position occupied by the London County Council in relation to the London coroners. The matter, however, may, with regard to all the points we have touched upon, be susceptible of explanation more complete than that which has at present been afforded. We do not question the desire of those concerned to make coroners' inquests effective and thorough, even if we doubt the advantages of the method adopted, and if without the fuller explanation suggested we are also sceptical as to its legality. With regard, however, to any possible alteration in the existing law we would point out that it was consolidated and re-enacted less than 20 years ago, and that no such change as that apparently desired by the London County Council could reasonably be made by Parliament without consulting to some extent the heads of the medical profession and ascertaining whether in their view the present system is unsatisfactory and if the proposed change is likely to effect an improvement.

◆

Sir Michael Foster and the Representation of the University of London

THE present position of affairs with regard to the representation of the University of London in Parliament has an interest for the medical profession as a whole as well as for those who are London graduates and members of Convocation. SIR MICHAEL FOSTER'S election in 1900 was in large measure the result of the desire of his constituents that the University member should be a man who could speak with authority in matters where science and learning are concerned, who would command attention in the House of Commons, and whose presence in Parliament would strengthen the administrative business of the country in a way which would hardly be possible in the case of a Member elected on political and party lines. This view was very strongly held by graduates in medicine and science, the great majority of whom supported Sir MICHAEL FOSTER, and it has been thoroughly justified by events. Sir MICHAEL FOSTER has come to occupy a strong position in the House of Commons, where it is recognised that he can not only express the views of an expert but can show the way by which expert knowledge can be turned to account in legislation and administration. The plea for science which he made in his speech on the Beer Bill of 1901—a speech believed to have influenced many votes—was a good illustration. Few men have a broader understanding of the principles which should guide the State in its relations with medicine and with matters of public health, and his keenness to secure amendments of sanitary legislation and improvement in the present condition of the public health service is well known. His work on the Royal Commissions on vaccination, sewage disposal, and tuberculosis in particular, has placed him in an exceptional position of influence when these matters come to occupy, as they shortly must, the serious attention of Parliament. We are certain that the announcement which Sir MICHAEL FOSTER made in his letter to Sir JOHN ROTTON published on Monday last, will be received with relief by his supporters and by the medical profession. We do not feel that Sir MICHAEL FOSTER'S published communications on the matter have been very lucid or fortunate, but we understand that he has been placed by others in a difficult position. The main point is that personal circumstances, which had seemed to make his resignation imperative, have altered sufficiently to enable him to retain the seat. He is prepared to do so, remaining as before practically independent of party claims, but as his action has resulted in three candidates having been put forward for the vacancy believed to be pending he has thought it right to ask Sir JOHN ROTTON, who acted as chairman of his committee at the last election, to ascertain the wish of the constituency. This is about to be effected by means of a circular letter addressed to the University voters. We have no doubt that a ready response will be forthcoming. It is a misfortune that a series of accidents has caused the three candidates, Sir JOHN WILLIAMS, Sir PHILIP MAGNUS, and Sir W. J. COLLINS and their respective supporters to be put to trouble and inconvenience, and it is evident that Sir MICHAEL FOSTER is very sensible of the awkward position which has arisen. But it would be a still greater misfortune to the University and to science if Sir MICHAEL FOSTER were no longer in the House of Commons.

[2] 9 & 10 Vict. c. 37.

[3] R. v. Finlay, Irish Reports 11, Common Law 498.

refreshments being provided *en route*), berth in sleeping car from Paris to Madrid (outward journey only), fees to hotel and railway servants, carriage drive on one day in Madrid, free conveyance of 56 pounds of baggage, omnibuses to and from hotels while with the conductor, and the services of a competent conductor who will undertake the general supervision of the arrangements throughout. In order that the necessary arrangements for sleeping car berth, hotel accommodation, conducting, and the like may be completed in good time it is requested that intending passengers will register their names by paying a deposit of £10 each as early as possible. When paying deposits passengers are requested to state the full name of each member and to say whether married couples, single ladies, or single gentlemen in order that the necessary rooms may be arranged. The balance of fare must be paid one week before the date of departure. Owing to the large demand for hotel accommodation in Madrid it has been necessary to reserve rooms in advance, the amount of the deposit therefore cannot be returned if for any reason the tour is not taken. Arrangements have also been made for an additional tour from Madrid to the South of Spain. This tour will occupy nine days, and Seville, Cordova, Granada, and the Alhambra will be visited. The inclusive fare is 18 guineas for members and their wives and 21 guineas for friends. The party will leave Madrid by the night express for Seville on Thursday, April 30th, and will arrive at Madrid again at 10.25 A.M. on Saturday, May 9th. Intending visitors to Spain are strongly advised to insure their luggage before leaving England and they must provide themselves with passports. Dr. Seelig, Ph.D., acting for the Voyages Pratiques of Paris, has also made arrangements for conveying members to the Congress. His address is 11, Ludgate-hill, London, E.C.

"SECRETIN."

IT has long been known that the passage of acid chyme from the stomach into the duodenum caused a flow of pancreatic juice and this has always been recognised as due to a so-called "local reflex." In a recent paper by Dr. E. H. Starling and Dr. W. M. Bayliss, read before the Pathological Society of London, of which an abstract is published in THE LANCET of Dec. 27th, 1902, p. 1753, they prove that the flow of pancreatic juice is not due to a "local reflex" but to the absorption into the blood of a product of the mucous membrane of the small intestine, which acting chemically on the cells of the pancreas produces a flow of pancreatic juice. This substance is produced in the mucous membrane as the result of the introduction of acid into the small intestine and can be obtained even from alcohol-dried mucous membrane by the action of weak acids. To this body Dr. Starling and Dr. Bayliss have given the name of secretin, although it has not yet been isolated in a pure condition. By injecting this secretin into the veins of animals they were able to produce a flow of pancreatic juice the quantity and time of production of which depended on the amount of secretin injected. Using this secretin for the artificial production of pancreatic juice they have been able to study the properties of this juice with greater accuracy than has hitherto been done and it has been found that of the three ferments present in pancreatic juice—viz., that which acts on starch, that which acts on fat, and that which acts on proteid—only the first two are active when the juice is collected from the duct of the gland and that in order to make the fluid active on proteid it is necessary to mix it with the succus entericus of the small intestine; this secretion contains a body first described by Chepowalnikow and named by him "enterokinase," which when added to pancreatic juice inactive on proteid converts its trypsinogen into an active tryptic ferment. Two further points have been brought out in this work which may have important clinical bearing—firstly, they showed that pancreatic juice in the absence of acid chyme in the small intestine produced an acute enteritis and they suggest that the introduction of enterokinase into the pancreatic duct might cause an acute pancreatitis owing to the production of an active tryptic ferment. It follows from this that though a flow of pancreatic juice may be induced by the injection of secretin there would be considerable danger of giving rise to an enteritis unless the time for such an injection was made to coincide with the time of passage of acid chyme from the stomach into the small intestine. The second point of interest is the observation by Pawlow that as long as the contents of the duodenum remain acid so long does the pylorus remain in a state of contraction and it is only when the contents of the duodenum have been rendered alkaline or neutral by the pancreatic secretion that the pylorus relaxes and allows a further flow of acid chyme from the stomach. The possible bearing of such an observation on the condition of hypertrophied pylorus in infants is one which is of considerable interest and suggests further lines of treatment for that affection.

CHOLERA IN EGYPT AND ELSEWHERE.

THE following figures show the distribution of cases of, and deaths from, cholera throughout Egypt during the week ending Dec. 15th. 60 cases of cholera have occurred during this period against 42 during the previous one, thus showing an increase of 18 cases. During the same week 41 persons have been found dead out of hospital and 10 have died in hospital, against 27 deaths out of hospital and 7 deaths in hospital during the past week, thus showing a total increase of 17 in the number of deaths. During the same period 59 cases have occurred in Alexandria, against 32 in the preceding week. Since Nov. 4th no cases of cholera have occurred in Cairo. For the week ending Dec. 22nd the figures are as follows: 17 cases of cholera occurred, against 60 in the preceding week, thus showing a diminution of 43 cases. During the same week 7 persons have been found dead out of hospital and 7 have died in hospital, against 41 deaths out of hospital and 10 deaths in hospital in the previous week, thus showing a total diminution of 37 in the number of deaths. The 17 cases above referred to have occurred at Alexandria. During the preceding week 59 cases occurred in that city.—For the week ending Dec. 29th, 49 cases of cholera occurred, against 17 in the previous week, thus showing an increase of 32 cases. During the same period 13 persons were found dead out of hospital and 19 died in hospital, against 7 deaths out of hospital and 7 died in hospital during the previous week, thus showing an increase of 18 in the number of deaths. During the same period 6 cases occurred at Alexandria, against 17 in the preceding week. A rather sharp outbreak was reported a few days ago from Khoos el Bousa, a small village about one hour's distance from Sohag and situated on the banks of Sohagia Canal. Dr. C. Goodman and a staff of well borers and disinfectors were at once ordered to the village. The Local Government Board for England has issued a circular dated Dec. 24th, 1902. The circular is addressed to all port sanitary authorities, to the King's habourmasters of dockyard ports, to all officers of customs, to all medical officers of health of the sanitary authorities aforesaid, to all masters of ships, to all pilots, and to all others whom it may concern. The circular sets forth the regulations made on Nov. 9th, 1896, concerning the flying of a yellow flag on every ship infected with cholera, yellow fever, or plague when such ship shall be within three miles of any part of the answer from Mrs Simms inclosing two bottles of a preparation called "Oxonia," for which the charge was 6*s* in addition to a fee of £2 2*s* Mrs Simms gave as a reference a person at Blackheath who promptly wrote a letter saying that his mother had been greatly relieved by using "Oxonia" for a similar complaint. Then the sufferer wisely communicated with his medical man who has forwarded the whole correspondence to us Mr Simms, of course, is a quack, but unfortunately the law cannot touch him unless perchance one of his "patients" were to die. But we do think that the conduct of the cleric in question is deserving of the gravest censure. He has raised false hopes in one who is in sore trouble and the only redeeming feature of the case is that the patient has sought orthodox medical relief in vain, so that Mr Simms and his backer cannot be accused of having delayed treatment But we would ask the Rev Mr —— how he would feel if we were to write to one of his flock who had sought spiritual consolation and who had been told, like Tannhäuser, that there was no help and advise him to seek aid from the Rev Giles Jowles or any other self constituted "minister" The Rev Mr ——'s position and abilities make his advice all the more dangerous when he is wrong, and we earnestly hope that he will take our remarks to heart.

THE DIFFUSIBILITY OF THE VIRUS OF SCARLET FEVER

UNDER the above heading we publish at p 92 of our present issue an interesting communication on a series of cases of scarlet fever which have been under the observation of Dr John Sutherland and which afford, he claims, evidences of "the wonderfully low diffusibility of the scarlet fever virus." Few epidemiologists will disagree with his contention that the virus of scarlet fever cannot retain its vitality indefinitely, as it is clear that there is a limitation of vital activity with regard to the virus of all communicable diseases. There will not, however, be the same unanimity of opinion with respect to Dr Sutherland's proposition that scarlet fever is "intensely contagious," and this notwithstanding his assertion that throughout the whole course of the epidemic to which he is referring he has only seen one instance of a susceptible child escaping the disease after contact with a desquamating case We are not quite clear whether he regards the desquamating cuticle as the vehicle of infection, but if he does so he will find that many modern authorities do not agree with him at the present moment, and it would be well that Dr Sutherland should hesitate before he generalises from the series of facts which have come beneath his notice. It would not be difficult to furnish another series of well attested facts to show that whatever the channel of infection may be it is not the desquamating cuticle In this connexion we would refer him to the large number of desquamating cases of scarlet fever which a few years ago were discharged without harm accruing from the Leicester Fever Hospital at a time when the beds at that institution were required for cases of small pox. The main thesis, however, which as far as we gather, he wishes to establish is that there is no danger of the conveyance of scarlet fever from one person to another through the agency of a third person such as a nurse or by any aerial convection of the infection from one room to another We do not quite follow Dr Sutherland's reasoning when he states that if healthy persons can convey the infection of scarlet fever we must assume that the virus has a separate existence after dissociation from its host. On the contrary, it seems to us only necessary to assume that the virus does not forthwith perish when so dissociated Has the virus of small pox a separate existence because its striking power is great or is the question solely one of resistance to atmospheric conditions? But Dr Sutherland's generalisations seem to be drawn from the consideration that in 48 families home isolation proved pre-eminently successful because "susceptible" children lived in each of the 48 houses and all escaped the disease, the term "susceptible" being used to imply children who had never to the knowledge of the parents suffered from the disease. According to him all these children were properly isolated either in one of three rooms on the ground floor or one of three rooms on the first floor We cannot help suggesting that these 48 families were somewhat remarkable if the heads thereof were able to prevent all intercourse between the sick child and the other "susceptible" children for from six to eight weeks. Our own experience of this class does not quite lead us to expect this exemplary behaviour on the part of children thus circumstanced The view we rather take of the whole series is that out of 10 + 34 + 48 = 92 families secondary cases occurred in 22. Dr Sutherland's statement that in Division III. the second case always occurred two days after exposure is so precise that we think he may have been misled on this point. This tendency to look for mathematical accuracy in the behaviour of an infectious disease, in which none of the factors necessary to bring it about can be regarded as exact quantities, is, we think, somewhat unfortunate It is surely sufficiently recognised that the majority of "susceptible" children who are exposed to scarlet fever fail to contract it forthwith, and similarly it is only infrequently that the disease is caused by a third person. But these facts hardly justify Dr Sutherland's practice of tacitly encouraging mothers to visit their neighbours' sick children.

THE FOURTEENTH INTERNATIONAL MEDICAL CONGRESS, MADRID

THE Fourteenth International Medical Congress will be held at Madrid from April 23rd to 30th Messrs. Thomas Cook have arranged the following itinerary, to be directed by experienced conductors, the inclusive cost being 33 guineas for members of the congress and their wives holding cards of invitation and 39 guineas for other friends of members of the congress The party will leave Charing Cross Station at 2.20 P M on Monday, April 20th, and will arrive in Paris at 9 15 P M. Hotel accommodation will commence with supper on arrival at the Hôtel du Palais d'Orsay on Monday night On Tuesday, April 21st, the journey will be continued by train de luxe from Paris, starting at noon Berths in the sleeping car will be reserved for the party and meals will be served *en route* Madrid will be reached about 3 P M on Wednesday, April 22nd, and those who apply first for tickets will be able to secure rooms at the Hôtel des Ambassadeurs. The return journey will commence on Thursday, April 30th, when the night express will be taken to Biarritz, where the party will stay until Saturday, May 2nd They will leave Biarritz by the 6 27 A.M express for Paris, arriving about 10 30 P M, luncheon and dinner being served *en route* A conductor will travel by the morning express *viâ* Boulogne and Folkestone, arriving in London early in the afternoon of Sunday, May 3rd The party may be left at Paris, as the holders of tickets may return at any time within 45 days The inclusive fare provides first-class tickets from London back to London, hotel accommodation and meals *en route*, commencing with supper in Paris on the outward journey and terminating with breakfast in Paris on the return (Sunday), according to the dates named in the itinerary (the accommodation consisting of bedroom, lights, and service, plain breakfast, table d'hôte luncheon, and dinner at table d'hôte, while travelling it will be necessary to modify this arrangement, the previous operation. Passing on to the experiences of Southend, Dr Nash states that the population of the borough roughly numbers about 30 000, of whom about 10,000 may be reckoned to be children under 15 years of age, and of these about 9000 are vaccinated Revaccination has been so freely resorted to during the last twelve months that 15,000 persons—i.e, one half of the population—may be assumed to have been vaccinated within the last 15 years The remaining 15,000 inhabitants may be divided into two groups—one of 13,000 who have not been vaccinated for over 15 years and one of 2000 unvaccinated. During the six months under review no case of small pox occurred in the group of 15,000 vaccinated within 15 years, 15 cases of small pox with one death occurred in the group of 13 000 not vaccinated for over 15 years, and 10 cases of small pox with four deaths occurred in the group of 2000 unvaccinated. Both the attack rate and the mortality rate were therefore very much higher among the unvaccinated than among the vaccinated.

THE RELATION OF RICKETS TO MENTAL ENFEEBLEMENT

THE relationship of rickets to certain forms of mental defect and weak mindedness has only been recently established. Trousseau in his famous lectures delivered at the Hôtel Dieu, Paris (1868), said that 'rachitics were of superior intelligence to other children of the same age," a statement now known to be only partially correct The mental condition of rachitic children has been closely studied by Eichhorst Bourneville, and others who have shown that in combination with liveliness of spirits and some precocity the rachitic child undoubtedly exhibits mental deficiency Dr Paul Renoult of Paris in a recent *Thèse de Paris* (1902) gives a careful study of the mental and cerebral conditions in rachitic children. Anatomically the rachitic skull is he says characterised by persistence of the fontanelles and late closure of the sutures while both swelling and softening of the bones of the cranial vault are also present The result is a protuberance of the frontal region of the head, giving rise to the so-called "Olympian forehead.' The parietal eminences or bosses are prominently developed while the intermediate sagittal suture is depressed and gutter like in appearance The rachitic skull tends to be large and brachycephalic in form, while the marked development of the parietal and frontal eminences often gives it a quadrate appearance Certain interesting anatomical differences are pointed out between the skull of the 'degenerate" and of the rachitic. The skull of the degenerate tends to be plagiocephalic—i.e, of asymmetrically oblique formation. Such a condition is never seen, adds Dr Renoult, in the rachitic skull. Scaphocephaly, or a keel like elevation of the sagittal line of the skull, is frequent in degenerates but is rare in rachitic subjects Finally hydrocephaly and microcephaly are characteristic of idiocy and the grosser forms of degeneracy but are not met with in rickets. As regards development of the face and jaws it is pointed out that whereas an asymmetrical face and a narrow and high arched palate are very characteristic of idiocy the former is not present in rickets though the latter is occasionally found A slight or moderate prognathism of the upper jaw is often associated with rickets. Abnormalities and malformations of the eyes, eyelids, ears and genital organs are not infrequently found in idiots and imbeciles but seldom in cases of rickets. On the other hand, characteristic osseous deformities of the spine (scoliosis and kyphosis) pelvis (flattening and obliquity), and lower limbs (curved tibiæ) are frequent in rickets and rare in idiocy From careful studies and measurements made on 430 idiots and imbeciles at the Bicêtre, Paris Dr Renoult has ascertained that the following osseous malformations or peculiarities of development are present in rickets beaded ribs in 24 cases, natiform skull in six cases, "Olympian forehead" in 10 cases, prognathism of the superior maxilla in three cases, scoliosis of the spine in five cases, incurved shape of the tibiæ in six cases, incurved shape of the femora in eight cases, and genu valgum in two cases Of the 430 patients examined 35 exhibited signs and symptoms of rickets, a proportion of nearly 12 per cent. The mental condition of these rachitic patients, says Dr Renoult, was not one of marked or low grade idiocy They were mostly imbecile or feeble minded Moreover, they did not present many or marked anatomical stigmata of degeneracy like the idiots The defect of intelligence in these rachitic patients is not regarded by Dr Renoult as congenital but as acquired in infancy as the result of gastro-intestinal or pulmonary infection. Infants, he adds are prone to catarrhal affections of the alimentary and respiratory tracts, subacute and persistent in character, attended by moderate febrile disturbance, and followed by marked symptoms of toxæmia. As a result of such toxæmia two sets of changes may be produced—viz., a rachitic alteration of the osseous structures and a degeneration of the cerebral nerve cells with partial arrest of their development The latter is the underlying cause of the mental deficiency—backwardness in speech and general intelligence—exhibited by the rachitic child Detailed accounts of necropsies of five cases are given which support the above views In conclusion, says Dr Renoult we are not entitled to say that rickets is the cause of weak mindedness but that both rickets and weak mindedness are sometimes due to the same infective processes and toxæmias of infancy

THE WINTER EXHIBITION AT BURLINGTON HOUSE

THE 1903 exhibition of works by the "Old Masters' certainly deserves its name, for the works shown go back to the time of Daedalus, say to 2000 B C Though none of the actual works of that versatile artist, who was somewhat comparable to Giotto, Leonardo da Vinci, M. Santos Dumont, and Sir Joseph Whitworth rolled into one, are exhibited, yet there are photographs and coloured drawings of works by him or by his pupils These exhibits are mostly the result of researches and excavations undertaken by Mr Arthur Evans between 1894 and 1902 inclusive But a few articles are shown by Mr D G Hogarth who has also been excavating in Crete. All the exhibits are of extraordinary interest and show the marvellous height to which the arts had risen in the time of Daedalus To begin with, the palace of Minos at Knossos, of which Daedalus was the architect, had a complete system of baths with a drainage system supplied with ventilating shafts and other sanitary arrangements on an almost modern plan Photographs are shown of a set of ivory statuettes representing youths leaping, in which the anatomical modelling and the muscular action are represented with extraordinary power and accuracy In a water colour drawing from a fresco we see a bull fight There are no horses in the ring but there is the bull, a magnificent animal together with three bull fighters Two of these are ladies They are scantily dressed, but what struck us most was the size of their waists Presuming that the Knossian lady was of about the same size as a modern Englishwoman her waist would have been about 12 inches in circumference. As the clothing of the lady in question consists simply of a corset made apparently of some golden fabric and a small scarf depending in front and behind from it, it would seem that the fulminations which the medical profession has for ages been hurling at tight stays can no longer be sustained on coast of England or Wales during the whole of the time between sunrise and sunset But the circular further orders the exhibition of a night signal as follows —

The master of every ship infected with cholera yellow fever or plague shall when the ship is within three miles of the coast of any part of England or Wales or is within the limit of a port, cause to be hoisted at the peak or other conspicuous place where it can be best seen and at a height of not less than 20 feet above the hull of the ship during the whole of the time between sunset and sunrise a night signal consisting of three lights which shall be arranged at a distance of not less than six feet apart in the form of an equilateral triangle, and of which the light at the apex of the triangle shall be white and the other lights at the ends of the base of the triangle shall be red in colour

THE METROPOLITAN WATER-SUPPLY

THE report on the condition of the metropolitan water supply during the month of October was issued by the Water Examiner at the beginning of December last. The Thames river water was in good condition during the whole of the month, and the level of the flow varied from a point one inch above to one six inches below the average summer level The rainfall at West Molesey during the month amounted to 1 55 inches. The average daily supply delivered from the Thames was 133 864 635 gallons, from the Lee 23 586,638 gallons, from 'springs" and wells 57,369,740 gallons, and from Hampstead and Highgate ponds 1295 gallons The total average daily supply was 214,822,308 gallons for an estimated population of 6,425 346, and this represents a daily consumption per head of 33 43 gallons The Chelsea Company delivered the largest amount per head daily (40 71 gallons) and the East London Company the smallest (28 17 gallons) The Lambeth and the Southwark and Vauxhall Companies distributed a larger amount of water per head than they did during the corresponding month of the year 1901 , all the other companies supplied a smaller amount The estimate as to the amount of water "delivered per head' is, we believe, arrived at from calculations as to the amount of water pumped from the distributing stations of the water companies In the case, therefore, of any serious defects in the distributing mains of the companies any water wasted through these defective mains is accounted for as having been used by the customers of the company It has been already pointed out in THE LANCET[1] that our present knowledge of the condition of the mains of the metropolitan water companies is distinctly fragmentary and it may be remembered that the August report of the Water Examiner recorded the occurrence of the curious fact that water from the Langham Hotel well had found its way into the mains of the West Middlesex Company As we remarked at the time of the issue of the report[2] a detailed account of this occurrence would have been of interest. The subsequent reports of the Water Examiner have failed to add to our knowledge on the point. During October the East London Company obtained supplies of water from the Southwark and Vauxhall Company and "from the New River Company aided by the Grand Junction and West Middlesex Companies" The average daily amount "passed on" by the Southwark and Vauxhall Company was 8,998 387 gallons The quantity "passed on" by the New River Company ' if spread over the whole of the month was equivalent to a daily average supply of 2 218 855 gallons ' The supply, however, was not 'spread over the whole of the month" but was given from the 10th to the 31st inclusive This is the account given in the body of the report of the Water Examiner The figures given under the heading "details of the metropolitan water supply and works of the water companies" are not exactly identical with those given above The table of details of the "average daily supply during the month in gallons" is to be found on page 8 column 5, and is as follows Supply from river Lee and storage, 6,721,139, from Thames, 8,480,000 , from wells, 14,953,861 , from Hanworth springs, 2,069,000 , from Thames per Southwark and Vauxhall Company, 8,992,000 As on previous occasions on which figures on the same subject have been given in different parts of the report, and have not been identical, no explanation is given as to how it happens that the discrepancy occurs It would add to the value of the report if the Water Examiner would in such a case append a few words to make the matter clear Theoretically, of course, the report is written for the instruction of the President of the Local Government Board and presumably he is satisfied with it. It might be interesting if a Member of Parliament would discover whether he understands and can explain it The proportions of brown tint observed in a two-foot tube ranged from 2 to 15 degrees of the standard in use "The water of the Lambeth Company exhibited the deepest average tint of brown." The Water Examiner states that "all the samples of water collected at the works of the companies were efficiently filtered" It is not stated that any sample of water collected at any "works" of any company was submitted for analysis to Dr T E Thorpe, F R.S , the chemist to the Local Government Board, nor does the Water Examiner say on what authority he makes the statement quoted above. Dr Thorpe examined during the month 14 samples of each company's water The samples which were collected on Oct. 13th were fully examined and the results of the analysis showed that the relative amount of organic impurity contained in the specimens is numerically represented as follows Kent, 9 , New River, 10 , Lambeth, 20 , Southwark and Vauxhall and Grand Junction, 21 , East London 22 , West Middlesex, 25 , and Chelsea 26. Dr Thorpe reports that "the East London Company's supply taken in a district served with water from the works at Sunbury contained an amount of organic impurity practically identical with the average found in the London waters but the proportion of oxidised nitrogen was, as usual, with the Sunbury supply distinctly higher The water," he adds, "was clear and of good chemical quality " It is a matter for congratulation that Dr Thorpe has bestowed special attention on the Sunbury supply of the East London Water Company, which, as far as we remember, has not hitherto been specially referred to in the Water Examiner's report although THE LANCET has many times given the reasons which make it desirable that the water from the filter beds should be analysed at periods during which the Thames is in flood Dr Thorpe's present report refers to an analysis taken when the Thames water was in a good condition. It will be interesting to compare this with an analysis made at a time when the Thames water is muddy

THE PREVALENCE OF SMALL-POX

IN his recently issued report on the occurrence of small pox in the borough of Southend on Sea from January to June, 1902, Dr J T C Nash, the medical officer of health, devotes considerable space to the important question of the efficiency of vaccination and revaccination Much misapprehension on this point no doubt exists in the community at large and fallacies ingeniously devised for the purpose of discrediting vaccination have by this means been made to pass current as incontrovertible truths The essential fact is, as Dr Nash points out, that vaccination does not consist in the mere insertion of lymph in an incision or scratch in the skin but in the production of a definite local effect which, in the case of primary vaccination consists of a vesicle possessing certain special characteristics and leaving a permanent, depressed, foveated scar In revaccination the local effects are slighter in proportion to the amount of residual immunity left in the individual from the ground that these articles are a modern innovation, nor can it be said that they impede muscular action. Possibly, however, the lady in question only girded herself in the fashion shown when she was in the ring, and so escaped gastroptosis, digestive troubles, a red nose, and fits of "the vapours"—all of which have been ascribed to tight stays of modern type

[2] THE LANCET Oct 18th 1902, p 1065

MEDICAL OFFICERS IN THE MERCHANT SERVICE

WITH reference to the case of Dr T W S Paterson, the particulars of which were reported in THE LANCET of Dec 13th, 1902, p. 1642, we learn by cable that the appeal of the Peninsular and Oriental Steamship Company against the decision of the magistrate was heard before the Appeal Court at Shanghai in December, 1902. The court reserved its decision, and on Jan 5th judgment was pronounced in favour of Dr Paterson The Peninsular and Oriental Company has given notice of appeal to the Privy Council. We are told that Dr Paterson has begun an action in the High Court of Justice in England against the Peninsular and Oriental Company, claiming damages for malicious prosecution

THE PROSTITUTION OF THE POST OFFICE

IN THE LANCET of Dec. 20th, 1902, p 1712, we referred to an abominable advertisement emanating from the United States in the form of an envelope inclosing an account of some coal tar derivative. The envelope was adorned with a large scarlet heart held by a skeleton hand. We forwarded a selection of these envelopes to His Majesty's Postmaster General and have been favoured with the following reply —

> GENTLEMEN —With reference to your letter of the 15th instant I am directed to inform you that the designs on the covers which you enclosed are not offensive within the meaning of the Act restraining the transmission of objectionable articles by post and in these circumstances the Postmaster-General is not able to take any steps such as you suggest to prevent their circulation
>
> I am Gentlemen your obedient Servant
>
> To the Editors of THE LANCET H BUXTON FORMAN

All we can say is that the sooner the law enables the Postmaster General to take steps for the stopping of the transmission by post of circulars of this nature the better it will be.

HEMI-HYPERTROPHY OF THE BODY WITH ENLARGEMENT OF THE OPPOSITE SIDE OF THE BRAIN

WE have recently called attention to a case of hemihypertrophy of the head and face associated with neurofibromata of the cranial nerves on that side, in which the hypertrophy was supposed to be due to an abnormal trophic influence of the affected nerves.[1] In the *Australasian Medical Gazette* for September another curious case of hemihypertrophy is recorded by Dr C Reissmann, and though widely different is analogous in that an abnormal trophic influence of nervous origin is again suggested. In this case the whole half of the body was affected and the associated nervous affection was enlargement of the opposite side of the brain. The patient was a boy, the youngest of a family of three. The mother was healthy and attributed the deformity to a shock which she received when two months pregnant on seeing a friend who was accidentally killed. The pregnancy continued to term, but the abdomen was larger than in the previous pregnancies and at the fifth and seventh months there were false labour pains. There was some difficulty in the labour in consequence of the size of the head and the child was delivered with forceps. He weighed 14 pounds On the fifth day after birth the right leg was noticed to be larger than the left, then it was found that the right arm and the right cheek were the larger At the age of five months he weighed 28 pounds. At the age of seven months he came under the observation of Dr Reissmann. The left side of the cranium was much larger than the right. The anterior fontanelle was widely patent and the posterior fontanelle was just patent. There was slight proptosis of the left eye. The ears were of equal length. The right cheek, jaw, and gums were distinctly larger than the left. The right side of the tongue was greatly enlarged, which enlargement when the organ was protruded caused deviation to the left. The right shoulder, arm, forearm, wrist, hand, fingers, and nails were much larger than the left. From the deltoid tubercle of the acromion to the styloid process of the ulna measured 20 centimetres on the right side and 17½ on the left. The enlargement appeared to involve skin, subcutaneous tissue, and muscle, and certainly involved bone. Little difference was noted in size between the two sides of the chest The right side of the abdomen was slightly larger than the left, particularly the skin and subcutaneous tissue which formed on the right side a loose fold above Poupart's ligament. There was an umbilical hernia. The right buttock, leg, foot, toes, and toe-nails were much larger than the left. The right leg was longer than the left by five centimetres The enlargement appeared to involve all the parts of the limb—skin, connective tissue, muscle, and bone. The muscular tone was good and equal on both sides, but the movements of the right side were more clumsy than those of the left, the attempt to grasp an object with the right arm was less decided then with the left. The knee jerks were not so readily obtained on the right side as on the left. Thus there was enlargement of almost the whole of the right side of the body and of the left side of the cranium, and therefore also of the left side of the brain. Dr Reissmann infers that there was also enlargement of the right side of the spinal cord, as it was improbable that the enlargement of the brain was due to mere overgrowth of neuroglia. He thinks that the nerve cells and their axis cylinders the upper neurons were enlarged. If the upper neurons were enlarged the lower ones were probably enlarged also But he seems to overlook the fact that a numerical increase of the neuron without enlargement is equally probable and would equally account for the facts This enlargement of one side of th brain and of the opposite side of the body is as curious a it is rare. No doubt it is rational to explain the latter by a abnormal trophic influence of the affected side of the brain But this only goes one step backwards The question arises how is the cerebral overgrowth to be explained ?

PRACTICAL ARMY HYGIENE IN THE FIELD

IT is not so much the want of sanitary knowledge as th difficulty or impracticability of applying it in the circum stances of war that has to be overcome in a campaig Apart from forced marches, night attacks, and hurried move ments often in entire ignorance of the position that a forc will occupy until it actually finds itself there, all of whic are more or less incidental to modern warfare, there has to be considered what is the best sanitary organisation to be adopted. The Army Hospital Services Inquiry Committee following the Egyptian campaign of 1882 recommended that a conservancy body should be organised in connexion with the Quartermaster General's department. Not only does the provision of a special sanitary corps presuppose the presence of a directing staff of well trained and competent officials to point out and to advise what has to be done, but it requires a properly organised executive of sanitary engineers and workmen with all the necessary appliances to do it If the latter are to consist largely of the civil element—navvies and artisans, for example, with carts, picks, and shovels—they would require, not being themselves armed or trained to arms, the protection of a military force during their operations, whereas a military and armed body of men could protect themselves and, if need be, could even add to the fighting strength of the army. As it is at present the men of the Royal Engineers and the soldiers belonging to different corps units acting under constituted authority are supposed to carry out all field and camp sanitary work, and it would seem that any special army sanitary corps would require to have a military organisation. The formation of such a corps would, no doubt, cause some initial expense, but it might very well exist in a skeleton stage during peace and be brought up to any given strength when required for war. Among the manifold changes and reforms in the army that are being talked of at the present time this subject of army sanitation in war is one that seems to us well worthy of being very carefully considered. If we are to take the results of the latest investigations into the causes of the spread of enteric fever as the basis of our sanitary action it will apparently have to be upon the lines of complete isolation of the sick—not easily to be accomplished in war.

---

[1] THE LANCET Dec. 20th 1902, p 1711

THE RECENT TRAGEDY AT THE FULHAM BATHS

THE death of two persons from electric shock at the Fulham public baths is a startling event which calls attention in a very emphatic way to the factors which determine the safety or danger of contacts with "live" wires. Like most electric-light fatalities the deaths were caused by leakage from a charged conductor to earth through the body. Contacts with conductors charged to 200 volts are not, as a rule, dangerous because the resistance of the body under ordinary conditions is sufficient to prevent the passage of more than a small current when that pressure is applied to it. Thus a person with dry hands and with dry boots on may touch a 200-volt conductor and feel little or nothing, even if he be standing upon a damp floor. In the victims of the Fulham accident all the natural protection which boots and dry hands provide were abolished. They were bathing, or about to bathe, their hands were wet with hot water, and they were standing in hot water or on wet concrete in the best of metallic connexion with earth through the waste pipes or the steel floor. It is well known that the moistening of the skin with hot water reduces its resistance enormously, so that a procedure of this kind is a regular preliminary to almost all therapeutic applications of electricity. When a patient is immersed in a bath of warm water a pressure of six or eight volts is sufficient to produce a commencement of tetanic rigidity in the muscles with an alternating current like that employed for electric lighting at Fulham, so that the effect of 200 volts under the conditions of the accident can readily be understood. The charged conductor with which contact was made seems to have been an iron bar or girder which traversed the tops of the partitions between the cubicles to strengthen and to support these partitions. Its connexion with the electric light wires was entirely accidental and it is difficult to say how long it may have been charged, thus constituting an unseen danger to those who used the baths. We are informed that it was not the electric-light casing which was the charged body, but some uncertainty exists as to this point in the newspaper reports, it appears, however, that contact was made by putting the hand on the top of the partition rather than by touching the metal electric-light wire casing which ran along the partitions at a lower level. It is worthy of note that in the case of one of the victims death was not instantaneous. He had time to call out and the caretaker was able to go to him and to break open the door and to try to detach him. His death seems to have been due to the prolonged action of a current which was not strong enough to kill instantaneously. Points to be learnt from the accidents are that touching electric-light switches should be avoided by those having a bath and that bath rooms should never have their electric-light fittings placed where they can be reached by a person in the bath, also that gas-pipes, water pipes, and drain pipes are "good earths" and that leakage currents from faulty electric fittings will be felt more strongly if contact is made simultaneously with two of these.

THE RESEARCH LABORATORIES AT THE UNIVERSITY OF LONDON

THE provisional arrangements for research in the physiological laboratory of the University of London have just been issued. The following courses of lectures will be delivered during January, February, and March, commencing on Tuesday, Jan. 20th, at 5 P.M. Dr. W. D. Halliburton on the Chemistry of Muscle and Nerve (Tuesdays), Dr. T. G. Brodie on the Circulation (Thursdays), and Dr. A. D. Waller on Experimental Pharmacology and the Action of Anæsthetics and Narcotics (Fridays). The laboratory has been established with the objects (1) of affording to the lecturers of the University of London and other duly accredited physiologists a place in which the results of current research can be presented by lectures and by demonstrations and (2) of giving to advanced students of physiology opportunity for the prosecution of research. The laboratory includes a lecture room, a workshop, a chemical room, a general laboratory, and two rooms assigned to the physiology of the special senses (inclusive of physiological psychology). Courses of research lectures with demonstrations are delivered during each academic term and a limited number of students are admitted as laboratory workers for advanced work. Applications "to occupy a laboratory table" should be made in the first instance to Dr. Waller, University of London, South Kensington.

THE LEAGUE OF MERCY

SIR HENRY C. BURDETT has just addressed to the press a letter not far short of 2000 words in length pleading for personal service and support for the League of Mercy, instituted about three years ago by the King. The league has revealed, he states, possibilities for good to London and Londoners quite apart from its monetary side—viz., that it gives everyone the opportunity to emulate the example of the Good Samaritan. All the officers joining pledge themselves to render personal service by inducing small givers to become associates. A subscription of one guinea a year, however, entitles the subscriber to be enrolled as an honorary member. Some members at first were inclined to resign on the ground that it was such a trouble to ask twenty people each to give at least 1s. to the hospitals, but when it was pointed out that this very trouble constituted their expression of thankfulness for the blessings they enjoyed these same members approached their work with a new and successful spirit and also inspired others. Sir H. Burdett says that everyone who at present subscribes to a hospital should become a member of the League, as its work by widening the area of givers must tend to lessen the burden entailed upon each in support of the hospitals. He will be glad to receive at the Lodge, Porchester square, London, W., the name and address of every Londoner who desires to find a channel in daily life for the expression of the sympathy felt by the healthy for the sick and suffering.

THE MOSQUITOES OF THE ATLANTIC ISLANDS

DR. MICHAEL GRABHAM of Jamaica, a zealous exponent of the West Indian culicidæ, is at work upon the mosquitoes of the Atlantic islands and has already obtained interesting results. The Azores have yielded no specific forms of any interest but from the Madeiras he has sent to the British Museum four or five new varieties of culex in addition to one or two already well known and described None of these, however, is of human interest, and one small one only is blood feeding in habit. In the case of the Canaries, however, matters are very different. Dr Grabham has found at Teneriffe, on the south side, a small anopheles identical with, or allied to, the malarial insect of the West Coast of Africa. This species is fairly common in the ravines and tanks He has found also the same mosquito as is concerned in the spread of yellow fever at Havana These discoveries are of great interest, for though the islands are free from malaria and yellow fever it is quite easy to contemplate either disease spreading when introduced if these subtle means of conveyance are at hand. Yellow fever was epidemic at Palma not many years ago and lasted two years Dr Grabham sends an interesting account of Guimar, 23 miles from Santa Cruz along a splendid road, but singularly destitute of vegetation He found the fertile valley of Guimar grandly situated, full of terraced cultivation, and with groves of orange trees bearing fruit luxuriantly Rain seldom falls and the hotel patients were sleeping out on the roofs or verandahs The water was supplied from a distant source in a concreted channel.

Sir Ernest Cassel has, it is announced, offered the sum of £40,000 for the investigation of ophthalmia and of other diseases of the eye among the natives of Egypt The chief object of the scheme is to train native medical men in the diagnosis and treatment of ophthalmic diseases, for native medical men alone can induce their poorer compatriots to learn habits of cleanliness and so to minimise, if not to prevent altogether, the ravages at present due to ophthalmia.

A course of ten lectures on the Mechanism of the Secretory Process will be delivered at University College, London, by Dr W M Bayliss in the physiological theatre on Mondays at 5 P M, beginning on Jan. 12th The lectures are open to all internal students of the University of London without fee, as well as to qualified medical men on presentation of their cards

SOME REFLECTIONS UPON THE PROFESSIONAL AND ETHICAL QUESTIONS ARISING OUT OF CONTRACT PRACTICE

By W Muir Smith, M D Glasg

The time limit, under the standing orders, apportioned to readers of papers and to subsequent speakers during the proceedings in the Section of Ethics at the annual meeting of the British Medical Association at Manchester was unfortunately all too short, leading to effete and incomplete conclusions Of ethics pure and simple there were almost none. The effect of this is evident from the terms of the resolution adopted on specific contract work [1] which runs as follows —

> That club and friendly society contract work is undesirable in the best interests of both patients and the profession

The utility of this resolution is more than obscure, in application it is of no effect, while it is negative by omissions which involve denial without directly denying—and by inference it implies—the existence of a positive. It is quite possible to convert the negative resolution into a positive proposition by inserting some form of qualifying condition or conditions to supply the omission as an amendment, accordingly—

> That in club and friendly society contract work only members whose average weekly income does not exceed 25s and who contribute 7s 6d per annum for that purpose shall be entitled to the benefits of medical attendance

affords positive data for discussing the system in some of its aspects and bearings. Club and friendly society contract practice has existed, does exist, and probably will continue to exist, and if abuses prevail surely these must either be amended or ended by practical measures.

"Contract" is an undertaking between two or more persons, in terms usually expressed verbally or in writing, to do a certain work or supply a certain article for a specified consideration The principle of contract not only pervades all, even the most menial, action in everyday life but also regulates the manner in which the obligation is discharged. Contract embodies a functionary "barter"—i.e., exchange of one thing for another The bargain is estimated according to the quality of personal judgment. The spirit of the parties in bartering is more or less selfish, the intention being to gain an advantage by questionable methods. In the best sense professional services are priceless The manner of discharging obligations varies according to the conception of moral responsibility To state that the standard of professional ability and integrity, even with an enhanced dignity thrown in, is commensurable with the amount of fee charged, is sheer nonsense Contract invites speculation, and it is the mercenary disposition of the bargaining spirit occasionally running riot in our midst that makes for evil ways in 'shady" transactions No doubt there are some who accept the existing conditions, see no harm and perhaps some profit in every form of contract work, deny any offence against moral certitudes or legal enactments, acclaim their right to liberty of conduct, and resent friendly admonitions as insults, determined that as preservers of their own well being they will rely upon their judgment for that end.

The conduct of professional life is regulated more by moral precept than by legal enactment. The General Medical Council in relation to State administration occupies a unique position A sessile appendage, yet recognised as an integral part of the Privy Council, its function therein is purely advisory in matters connected with or affecting the profession Devoid of legal power, unfettered by stereotyped formulary—being a law unto itself—judgment on questions of conduct is based upon, or at least is influenced by, prevailing opinion—i.e., the consensus of professional opinion—for the time being on any contentious subject, and which becomes binding on the whole body If the composition of the General Medical Council be invidious the manner of administration is very democratic, while its disciplinary powers, being unlimited, could be used more arbitrarily than the edict of a despot Thus the State in absolute faith hands over certain administrative work to the General Medical Council, and so it comes to pass that the general profession have to frame their own laws and shoulder the responsibility of the General Medical Council's actions This ever increasing condemnation, being a sincere desire to protect the public from imposition and to conserve professional integrity is the outcome of years of discussion and is declaimed with such persistence and effect that the volume of righteous repudiation can no longer be ignored

From their peculiar nature the public are unable to appreciate the quality of services tendered The contract practitioner taking advantage of his opportunity performs his duties mechanically and prescribes inferior or unsuitable substitutes, soothing his conscience in the reflection that such conditions preclude giving of his skill the best and treating as he should if the pay were more. The General Medical Council has already issued a warning to the profession, threatening all the penalties of the Yarmouth case on individual offenders This sounds as if coercion might remedy the evil by restricting individual liberty, a principle apparently contrary to the best form of constitutional government. Liberty if uncontrolled becomes a licence and a licence unrestrained becomes an abuse, a grave injustice, and an injury to others, hence the law steps in to check its mad career and to protect the interests of others Because the law does not interfere with a man's action that man is not necessarily free. It is a fact that extensions of law need not imply diminution of freedom, but quite the opposite There is a moral restriction as well as a legal restriction. The profession bends to its will all who form part of it and the practitioner must submit to the customs and formalities of his calling Liberty to go to practise elsewhere by reason of fancied grievance is an empty privilege when the conditions are everywhere the same. No one can be free to decide for himself the conditions of his employment. Before receiving State licence to practise every probationer must subscribe to certain specified conditions regulating his conduct in professional life, *which conditions were not of his own framing nor those of any individual, but a solemn covenant binding on every member*

---

[1] The Lancet August 9th 1902, p 391.

It is more justifiable that the majority should impose their will on the minority by means of a law for the ultimate good of all than that the minority through their economic power should impose their will on the majority to the common detriment, moreover, that which is acclaimed by the majority as acceptable must either in whole or part benefit the minority where a community of interests exists

In any contract two at least are required to make a bargain. Habits and customs growing up with childhood, youth and manhood become an integral part of the generation and are likely to be more deeply rooted in the nation's sentiment if handed down through successive generations. The condition of the poorer classes seems in many respects scarcely bettered. The progress of education with the experience gained of local self government and the organisation and management of numerous coöperative societies, &c., has failed to give that amount of self enlightenment which is necessary to provide efficiency for the needs of the case. It seems as if the self reliance and enterprise of at least a very considerable portion of the working classes are insufficient to overcome difficulties without help

Poverty exists because men follow their lower instincts without due consideration. Civilisation in every respect is a struggle against the animal nature and the degree attained is proportionate to the amount of restraint exercised. The habitual drunkard although condemned and despised by all professing good moral individuals, meets with their sympathy and benevolence, nay more, this very vice is one of the chief grounds used as an appeal for assistance towards the needs of a large family depending on him for support. Experience shows that the mass of mankind never judge moral questions for themselves and cannot or will not discriminate between right and wrong even when plainly told. The benevolent are equally culpable, aiding and abetting the drunkard's addiction to the vice, being too lazy to determine aright and too disinclined in the exercise of reason and judgment to put them to the test.

Everyone has a right to live. Many because of poverty's pinch could scarcely exist were it not for extraneous forms of help—i.e. parish relief or the doles of private benevolence. To give monetary assistance or in some measure to relieve the people of financial obligation, whether under the cloak of charity or in the nature of employment, without exacting a specified obligation in return, so that prudential motives shall act powerfully on them, is to benefit without attaining the object. When payment is made for work found as charity only inefficiency will be likely to be the result.

Before the Poor law enactment facts were experimentally ascertained in scattered parishes of England whereby it was shown that the amount of support guaranteed could be freed from any injurious effects upon the minds and habits of the people if relief, though ample in respect of necessaries, was accompanied by conditions which they disliked, consisting of restraints on their freedom and foregoing some of their indulgences Subsidies in aid of income enable the people to live with less remuneration by their efforts and in the long run lead to lowering of the standard of wages by the equivalent amount of subsidy No extraneous assistance can be of the least benefit which does not operate on the minds and through the habits of the people. Thus "contract" practice, a form of subsidy, in giving professional services for almost nothing affects prejudicially the habits of the people. It is universally admitted that the amount is wholly inadequate in return and disproportionate to the possibilities of the people It must either enable the people to live on lower wages, to gratify their indulgences, or to add to their comforts. If the standard of wages is lowered the employer of labour will probably be the chief beneficiary In sequence, if wages are lower the standard of professional tariff will also be reduced. Thus, this form of practice subsidises the industries of the country at the cost of a tax on the whole profession, moreover it is a grave source of evil, prejudicial to professional interests and morality, in conduct discreditable, and reprehensible for the honour of all concerned Further, it is of no benefit to the people but quite the reverse, inasmuch as the incentive to exercise self restraint is suppressed, while the stimulus to foster self reliance is withdrawn, thereby deleting from the people's life those aspirations which make most for a nation's greatness The cause of the whole mischief arising from this specified form of practice is the insufficient and unequal rate of remuneration The fault lies, not in the principle, but in the system It is impossible for the public alone to adjust the balance, therefore the profession must take the matter in hand and endeavour to coöperate with the public.

Three causes, then, combine to justify interference. 1 The conditions under which the profession is bound up with certain specified forms of contract practice are in many respects so bad that to tolerate them longer is scarcely possible, and that the *laissez faire* policy is not likely to bring about a cure. 2 Self reliance is a powerful force, but not powerful enough to remedy unaided the evils that affect the profession 3 The General Medical Council is more determined than ever to regulate the conduct of the profession consonantly with its best interests, and experience has shown that such regulation is neither inconsistent with its well being or prosperity nor tends to undermine self reliance nor operates prejudicially to the general welfare.

The principle of insurance seems still the more efficient method, but conducted on lines with necessary safeguards which at present do not generally apply Even a wage-limit would not be a sufficiently wholesome restriction. Whatever system be adopted combination must be the basis and "pooling" the method of insurance by the people On the other side, the profession must be in absolute agreement not only locally but generally It is hopeless to expect, even with a most adaptable sliding scale of wage limit, a satisfactory solution so long as the principle of "barter" is retained—that is, exchange by questionable means, a bad bargain, cheating The proposition already stated, therefore, could not be acceptable, so that the resolution still stands This practically amounts to an abolition of the whole system Another amendment might probably meet the requirements of the case —

> That club and friendly society contract work is undesirable in the best interests of both patients and the profession unless provision be made for payment of individual service according to a scale of fixed charges

This proposition provides a method for outflanking two obstacles—viz., an annual compounding payment and a wage limit—while it embodies two essential principles—namely, the independence of the medical attendant and payment for individual service In operation this system might be modeled on the lines of the National Deposit Friendly Society under "medical pay" with this alteration—that one common fund be substituted into which all the contributions of the members should be "pooled" and from which all medical charges should be paid.

According to the thirty-third annual report of the National Deposit Friendly Society for the year ending Dec. 31st, 1901, out of 68,400 benefit members (compared with 56,120 in 1900) 13 087 drew medical pay to the amount of £8410, being an average of 12*s* 1*d* per *sick* member As a basis for calculating the amount of individual contribution requisite to meet the charge of £8410, let the membership for the year 1900 (56,120) be taken as the total number entitled to full *financial* benefit for the year 1901, it gives 3*s* per member per annum as the equivalent levy and, as seen, this is on a very liberal scale The National Deposit Friendly Society admitting female members also may be taken as a fair sample for average club statistics No scheme will ever be perfect and so this society has not commanded universal favour, but when compared with the payment of an annual dole ranging from 2*s* 6*d* in some districts to 6*s* in others and given in the spirit of "make anything out of that you can," surely it is preferable.

The difficulty clinging round the solution of wage limit is largely due to the fact that no friendly society can debar a candidate from membership on the ground of wealth alone. When once enrolled he can insist upon all the benefits, privileges and rights which are extended to other members. Under the scale of the Eastbourne Provident Medical Association single members with a wage limit of 20*s* contribute 2*d* per week, or 8*s* 8*d* per annum, and the lowest premium received in family membership is 1*d*, or 4*s* 4*d* By comparison the advantage to the member would be much in favour of the "separate service" system. If the individual contribution were raised to, say, 5*s* —and that surely would not entail any hardship—it would provide a liberal advance on the scale of the National Deposit Friendly Society and no single service should command less than 2*s* 6*d* Compared with existing conditions the advantages should be obvious—independence, equity, efficiency, and general acceptance.

In the foregoing main principles only have been suggested, details have purposely been omitted, being considered secondary and liable, if stated, to obscure the main issues. Written with a suggestive object, in treatment this subject does not lay claim to originality in any part of the compilation, but it embodies a few generally accepted principles of ethics and economics The irony of fate mocks every genuine effort in professional reform. True, money is at the root of this as of all evil, but yet the motive which inspires the movement and the object kept in view—'tis not for money's sake nor greed of gain, but to remove the curse, the evil deed that's done contingent on that need. In time the remedy will be found, not in an exhibition of supercilious self unction, but in a generous application of unselfish deeds, each in his little sphere acting his humble part, with honest heart and ready hand, helping the other to lead the best professional life—the highest privilege of professional brotherhood.

THE NOBEL PRIZE FOR MEDICINE, 1902

As our readers are aware the Nobel Prize for Medicine in 1902 was awarded to Major Ronald Ross, C B, F R S, Lecturer on Tropical Medicine, University College, Liverpool An address was delivered by Professor Count Morner, Rector at the Caroline Institute, Stockholm, on the occasion of the award, of which the following is a translation —

Among the stipulations Alfred Nobel set forth in his will on which the Nobel foundation is based that concerning the international character of the prizes occupies an important place This proves not only his love of mankind and his wish induced thereby that we should regard one another as brethren but it also is a witness of his extensive and prescient views especially concerning medical science and its advancement

All the branches of medical science and their promoters in different countries have ultimately the same aim that of gaining the most thorough knowledge possible both about the human body and the processes in it as also about the noxious influences and the means for their prevention All medical workers unite their forces in pursuing that aim and in doing so feel members of one great fellowship Nevertheless the different fields of medical science lie at such distance one from another that the individual worker on many occasions must look afar in the attempt to get a thorough view of the progress of the work

With respect to diseases they are often of different kinds and importance in divers regions of the world For instance malaria is nowadays of little importance here in Sweden whereas it is a veritable scourge in other regions For elucidating this question by an instance from a European country it may be mentioned that in Italy of late the annual average deaths from malaria have been about 15 000 and the yearly number of the cases is calculated as about 2 000 000 Still more overwhelming are the numbers from India. Of the British army amounting to about 178 000 men close upon 76 000 men were admitted into hospital for malarial fever in the year 1897 In this single year the mortality from fever among the civil population in India amounted to a huge total it being a well known fact that malaria dominates so severely vast territories that it causes the very greatest difficulties for the cultivation of lands which but for malaria are specially favoured by nature.

The questions of the real nature of malaria, its origin its manner of entering the organism, and the consequent question of the possibility of preventing this disease are all of the greatest importance and have from remote ages occupied investigators for a long time without success, A very important discovery concerning malaria was made rather more than 20 years ago when Laveran, a French army surgeon ascertained that malaria is a parasitic disease caused by a very low form of animal life which he found in the blood of malarious patients. By this discovery the name of Laveran has for ever become renowned in the history of malaria. Research about malaria in the last two decades has chiefly been based on Laveran's discovery Science has thereby been enriched with many an important fact We have gained knowledge of the different forms of the malarial parasite in blood. We have found that it differs in the special forms of the disease We have learned the relations between the parasite and the red blood corpuscles in which it is chiefly to be found We have furthermore been able to survey the manner in which it multiplies in the blood the Italian investigator Golgi has in this respect revealed the remarkable fact that the periodicity of the malarial attacks depends on the appearance of new generations of the parasite in the blood. We have moreover found allied parasites in the blood of several mammals and birds.

The important question previously mentioned as to the possibility of the malarial parasite living outside the body and its way of obtaining entrance into the blood remained unanswered. For some reasons among others owing to various facts that were known concerning other parasites of an animal nature it was supposed that the malarial parasite in some way leaves the blood so as to exist in some form in nature probably as a parasite of another creature. As nothing indicated that the parasite was to be found in the secretions or excretions it was suggested that suctorial insects might assist in carrying the parasite to a place where it had to pass the aforementioned part of its life-cycle. Attention was therefore directed to the mosquito, which was thus supposed to spread the malarious infection. The importance of the mosquito in this respect has now been proved In this case, as in several others tradition anticipated science it is even said that negroes in East Africa use the same name for the mosquito and for malaria.

The mosquito theory of malaria was introduced to science by King no less than 18 years ago The theory, however remained a conjecture founded only on some suggestions given by epidemiological observations. The attempts made in Italy in the early nineties with the aim of experimentally examining the theory and eventually proving it to be true gave results that seemed to be anything but encouraging and more likely to prevent the investigation from following this line

A person whom we must deem of great merit concerning the solution of the problem is the English investigator Patrick Manson. It was a change in the appearance of the parasite which was sometimes observed to occur as the blood is shed, that Manson especially regarded as the first stage of its life outside the body This phenomenon has afterwards been shown by the American pathologist MacCallum to imply an act of fecundation of the parasite Manson was moreover guided by his experience regarding another parasite of the blood, a little worm (filaria) the transference of which from one part of its life-cycle to another he had found effected by the mosquito and more particularly by certain species of the mosquito By the views set forth on malaria and by exciting expectation that the solution of the malaria problem was to be found in the direction he indicated, Manson gave impulse to the further testing of the mosquito theory and at last to its being established Manson who lived in England had no opportunity of taking up the experimental work of the problem. The solution came from India

It was an English army surgeon in India, Ronald Ross, who impressed by Manson's induction, undertook the experimental testing of the matter Critically arranging his experiments he caused mosquitoes that were hatched from larvæ in the laboratory to bite malarious patients and endeavoured to follow the parasite in the body of the mosquitoes. The results of the first two years labour although assiduous and scrupulous gave little promise of success. But in August 1897 all at once he made vast progress towards his aim. While experimenting with another less common species of mosquito in the wall of its stomach he found bodies that very probably were an evolutionary stage of the human malarial parasite Ross being prevented by circumstances from pursuing his plan of studying the malarial parasite of man, continued his work with an allied malarial parasite of birds. The result was that he could not only confirm his discovery concerning human malaria as he found corresponding facts for the avian malaria, but he also in a short time succeeded in revealing the further development of the avian malarial parasite in the body of the mosquito This development is briefly as follows. In the stomach of the mosquito at first a process of fecundation takes place The form of the parasite thereby produced penetrates the stomach wall, imbedded in which it grows to bodies projecting like buttons from the outer surface of the stomach In these bodies a large number of elongated organisms sporozoites, are formed On the consequent bursting of the said bodies the sporozoites escape into the general body cavity of the mosquito and accumulate in the salivary or poison glands, which are in connexion with the proboscis with which the bites of the insect are inflicted A bite of the mosquito at that time inoculates the parasite and if the individual is susceptible to the parasite this develops in the usual manner

Ross's discoveries about malaria were immediately followed by a series of important works Thus, the Italian investigator Grassi, in association with his colleagues Bignami and Bastianelli proved that the human malarial parasite not only in its early stage, already detected by Ross but also in its further development undergoes the same evolution that Ross described for the growth of the avian malarial parasite in the body of the mosquito Grassi also has precisely defined the species of mosquito that are of import for the malaria of man Many a valuable work besides these have been issued by Ross by the Italian investigators by Robert Koch and by many others—works by which not only has our knowledge of the malarial parasite been enlarged, but this knowledge has been made useful in combating and preventing malarial disease

The eminent scientific value of Ross's work its importance as a basis for the success of the recent investigations into malaria, its rich contents as regards the art of medical practice, and especially hygiene will be obvious from the above

It is owing to these merits that the professional staff of the Caroline Medico-Chirurgical Institute have decided to allot the medical Nobel prize of this year to Ronald Ross

ROYAL ARMY MEDICAL CORPS FUND

THE second meeting of the committee of the Army Medical Services Fund for Perpetuating the Memory of Distinguished Officers (henceforward to be known as the "Royal Army Medical Corps Fund") was held at 68, Victoria street, London, S W, on Dec. 16th, when a permanent committee was elected, it being decided that the process of filling the places of those retiring should be automatic, the Director General of the Army Medical Service being always the chairman. With regard to retired officers it was agreed that the present representatives—Surgeon General J B C Reade, C B, K H S, Surgeon General H Skey Muir, C B, and Lieutenant-Colonel J F Beattie—should retain their seats and that when vacancies occurred they should be filled by the votes of retired officers subscribing to the Fund It was announced that Surgeon-General

Sir James A. Hanbury, K.C B A.M S had retired from the committee on account of his health As regards officers on the active list it was agreed that the holders for the time being of the following appointments should be *ex-officio* members of the committee the Deputy Director-General of the Army Medical Service (vice-chairman), the Deputy Assistant Director General of the Army Medical Service, the principal medical officer of the First Army Corps, the principal medical officer of the Home District, the commandant of the Medical Staff College, the professor of hygiene, Medical Staff College, the quartermaster, Medical Store Depôt Woolwich, and one junior captain of the Royal Army Medical Corps (not necessarily a member of their mess) to be elected by the officers of the Royal Army Medical Corps mess at Aldershot

The question of a concise name for the Fund was then discussed. 43 designations had been proposed by subscribers, many of them of a lengthy character The title, "Royal Army Medical Corps Fund," gained the largest number of supporters and it was resolved that the Fund should be called by that name.

The votes of subscribers to fix the amount of the annual subscription of officers on the active list were then taken. Out of a total of 339 votes 195 were in favour of £1 per annum and 144 in favour of one day's pay of each rank. The question of a reduction of subscriptions for lieutenants was negatived by the votes of officers of that rank.

A proposal by Colonel R. EXHAM, C B, R.A.M.C, that a fund should be started to meet cases of distress among widows and children of deceased officers of the Corps was negatived, it being felt that the Royal Army Medical Corps Fund was not yet in a position to undertake such large financial matters as were involved in the proposal, but a proposition by Colonel J J MACNAMARA, R A.M.C, that the Fund should take up the question of a compassionate fund for warrant officers, non commissioned officers, and men of the Corps, and their wives and families on or off the strength, was agreed to in principle by the committee The following sub-committee was appointed fully to consider and to report to the committee upon the subject and to deal in its report with such funds relating to the matter as already exist—Surgeon General Muir C B, the principal medical officer of the First Army Corps, the commandant of the Medical Staff College, Lieutenant-Colonel Beattie, and the deputy assistant director general of the Army Medical Service The same sub-committee was also requested to draw up a report containing a scheme for the due administration of each of the objects embraced by the Fund, having regard to the existing conditions of certain funds and to the fact that retired officers have in many cases limited their subscriptions to certain objects.

In recognition of the efforts of the late Surgeon General J B Hamilton, A.M.S. in behalf of the interests of the Royal Army Medical Corps, it was resolved that a brass memorial tablet to the memory of that officer should be erected at a cost not exceeding £20

MEDICINE AND THE LAW

The Medical Officer of the Ballachulish Slate Quarries

REFERENCE has already been made in THE LANCET to the dispute between the directors of the Ballachulish Slate Quarries, Limited, and Dr Lachlan Grant, of West Laroch, Ballachulish. Judgment has now been given by Lord Kyllachy, after hearing argument, upon the points at issue between the parties in the Outer House of the Court of Session In contracting with the directors to act as medical officer to their quarrymen in return for a fixed salary Dr Grant further agreed to accept a month's notice to terminate his services and also bound himself upon such termination to give up any local appointments and other practice in the immediate neighbourhood of Ballachulish. Notice of dismissal was given to Dr. Grant, but he has consistently contended that it was given arbitrarily and for no good cause and has consequently refused to carry out the agreement not to practise medicine any more in the locality Several points were raised before Lord Kyllachy involving the right of the directors to sue (owing to changed relations between them and their men which have arisen in consequence of the dispute with Dr Grant) and also as to the reasonableness of the restriction imposed. Lord Kyllachy, after considering his decision, gave judgment on Jan 2nd against Dr Grant, holding that he was bound by the agreement which he had made and ordered him to pay the expenses of the pursuers in the action

Unsatisfactory Inquests.

We have before us accounts of two inquests taken from the *Bradford Daily Observer* of Dec. 16th and the *Keighley News* of Dec. 27th. These seem to show that whereas the London County Council and the coroner for South west London are dissatisfied with the provisions of the law for the obtaining of medical evidence and the making of post-mortem examinations on the ground that they are insufficient, other coroners may regard post-mortem examinations and medical evidence generally as altogether unnecessary superfluities. In the one case a woman named Stirk was found dead in her husband's house. A medical man gave evidence that there were marks on her throat which might have been caused by fingernails, also a lump on the back, and another on the top of the head, and stated that these injuries or some of them might have been the cause of death and they might not We do not wonder that the jury found that the evidence was insufficient to enable them to say whether the injuries caused were responsible for the death or whether the woman died from natural causes, but it will be remembered that without the coroner's instruction the medical man had no right to make a post-mortem examination. In the other case investigated at an inquest at Keighley police-station a man was found dying in the street, but as his body was not identified we cannot give his name. A witness who stated that he knew a man answering to his description was not taken to see the body and there was no medical evidence whatever The *Bradford Daily Observer* thus concludes its account of these remarkable proceedings "The coroner proceeded to read a verdict to the effect that the man died from natural causes and not from violence. This was agreed to by the jury as their verdict. The coroner at the conclusion of the inquiry said he hoped the press would not give undue prominence to the fact that there was no direct evidence of identification." The publication of this naïve request seems to be the best method of commenting upon the matter, but we would remind juries that it is for them, if they are dissatisfied with the medical evidence or the lack of it, to express their view and to insist upon the coroner obtaining the witness suggested by them.

METROPOLITAN HOSPITAL SUNDAY FUND—At the Mansion House on Jan. 6th a meeting of the council of the Metropolitan Hospital Sunday Fund was held under the presidency of the Lord Mayor Among those present were Sir William S Church, Bart., K C B, President of the Royal College of Physicians of London, Sir William Broadbent, Bart., K.C V O, Sir E. Durning-Lawrence, M.P, Mr C E Tritton, M.P, Canon McCormick, Canon Rhodes Bristow, the Rev Dr Rigg, Mr Wakley, and Mr. Thomas Bryant. Mr J Hampton Hale was elected to fill a vacancy on the general purposes committee, the members of other committees were re-elected and the honorary secretaries, the honorary solicitor, and the honorary auditors were re-appointed Sir Edmund Hay Currie, the secretary to the Fund, referring to the distribution of surgical appliance orders and hospital letters, said that he should be glad if more members of the council would attend the special committee meeting in order that they might see the work that was being done In his reply to a vote of thanks, the Lord Mayor said that a meeting would be held at the Mansion House on June 8th for the purpose of calling wider attention to the objects of the Metropolitan Hospital Sunday Fund when he hoped to induce some speakers of great eloquence to address the meeting which would be reported and the proceedings published all over the country 25 per cent. of the patients who attended the large hospitals in London and no less than 60 per cent. of the patients who attended the smaller hospitals came from districts outside London which contributed nothing whatever to the Fund. Of the 104 000 in patients of the London hospitals last year 25,000 came from districts outside the 12-mile radius. The cost of treatment and maintenance of these patients was £150,000 Some 700 letters had been written to the country clergy on the matter but so far the replies had not been at all satisfactory

THE LANCET RELIEF FUND.

Almoners

THIS Fund, which came into operation on the 1st of February, 1889, has for its Almoners the President of the Royal College of Physicians of London (Sir WILLIAM SELBY CHURCH, Bart, K.C B, M D Oxon., F R C P Lond.), the President of the Royal College of Surgeons of England (Sir HENRY GREENWAY HOWSE, M B Lond F R C S Eng), the President of the General Medical Council (Sir WILLIAM TURNER, K.C B., M B Lond., F R C S Eng and Edin., F R S), Mr THOMAS WAKLEY F R C S Eng, and Mr THOMAS WAKLEY, jun, L R C P Lond, with Sir HENRY PITMAN, M D Cantab, F R C P Lond, as Honorary Auditor

Scope of the Fund

FOR the guidance of those seeking assistance and of those desirous of recommending deserving cases, it may be useful to record that THE LANCET Relief Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, which is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners or to their widows and orphans, in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. In the case of widows and orphans, in order to come within the scope of the Fund, the death of the Husband or Father must have been of recent occurrence.

Chronic Cases ineligible

WHEN the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established, and as a result the majority of the earlier applications, being cases of *chronic* distress and not coming therefore under the designation of *emergency*, could not be entertained. As the Almoners still receive applications for assistance for cases which are obviously of a *chronic* character, it is thought advisable to append a statement concerning cases of this nature which appeared in THE LANCET of Feb 16th, 1889 —

> We are requested by the Almoners to state that *from the character of a number of the applications received both personally and by letter* for relief it is evident that in many cases the object for which this Fund has been established is not quite clearly understood, and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established which is to afford prompt aid to registered medical practitioners or to the widows or orphans of members of the profession who in consequence of the supervention of some unexpected emergency which is not likely to recur have pressing need of immediate and temporary pecuniary relief"—

And who, it may be again pointed out, are likely to be permanently benefited thereby

FOURTEENTH ANNUAL REPORT of the ALMONERS

For the year ending December 31, 1902

IN presenting their Fourteenth Annual Report, the Almoners have to record that the balance in hand on Dec 31st, 1901 was £269 7*s* 4*d*, to which on Jan 1st, 1902 the Proprietors of THE LANCET added the sum of £300, making, with £42 repaid on loans, a total sum of £611 7*s* 4*d* available for grants during the year 1902.

The number of applications for assistance received by the Almoners during the year was 73—a falling off of nine as compared with those received in the previous year—of which 27 were so obviously outside the scope of the Fund that they were rejected by the Secretary by virtue of the discretionary power conferred upon him by the Almoners at their meeting on Jan 1st 1890, 11 were rejected by the Almoners after due consideration, in 11 cases Forms were sent but were not returned—probably the applicants recognised that their cases were outside the scope of the Fund, and 24 applicants were relieved by gifts of money ranging from £5 to £30 No loans were granted during the year The relief of the 24 cases, a detailed list of which is given in the accompanying Statement of Accounts involved the expenditure of the sum of £318—a sum just above the normal income of the year, omitting balances brought forward and possible receipts from loans.

Letters continue to be received by the Almoners from some of those whom they have helped, expressing their gratitude for the relief which has enabled them to mitigate, and in not a few cases to overcome, their difficulties, and thus testifying to a gratifying feature in the administration of the Fund As an instance of this, and one typical of many, may be cited a communication received from Case No 560, in which the recipient of relief says "The gift will be such a help to me in my terrible trouble. What I should have done without it I dare not pause to think

The promptness of the relief afforded to applicants is also a feature to which the Almoners continue to give their particular attention, and in this connexion it may not be uninteresting to record the fact that on several occasions the Almoners have been able to consider cases and to grant relief on the actual day on which the application was received. Case No 536 wrote "It was doubly welcome, because so prompt"

In their Report last year the Almoners referred to the gradually decreasing number of loans advanced from the Fund, pointing out that they were becoming more and more averse to affording assistance by this means, as their experience was that in but very few cases were loans ever repaid Consequently, no relief by means of loans was afforded last year, but the Almoners record with satisfaction that during the period under review loans to the amount of £42 were repaid The repayment of one loan (Case No 336 granted in 1896) was accompanied by a note stating that "I must thank the Almoners again for their great kindness in the past, I am very anxious to send it back to-night because I am ill." The Almoners have also received a communication from the West Indies from the widow of a medical man, announcing his death, and expressing her desire to repay a loan which her husband had from the Fund in 1893.

There are still far too many applications received for assistance for what are obviously "chronic" cases, a large proportion of the 27 cases rejected by the Secretary coming under this heading It cannot be too emphatically reiterated that THE LANCET Relief Fund exists to meet cases of *sudden emergency*, where timely help will tide the practitioner over his unforeseen (and too often unprovided for) difficulties, or afford his widow and orphans (alas, again too often unprovided for) a few weeks' respite from the more pressing financial cares of their unhappy position.

In conclusion, the Almoners desire to state that they will at all times be glad to have their attention called to any cases of genuine distress coming within the scope of the Fund, but they trust that those recommending cases or giving testimonials will first take steps to satisfy themselves of the *bona fides* of such cases before endorsing them. In the administration of such a Fund as this the Almoners are of necessity largely guided in their decisions by the testimonials accompanying the applications

I find by the Bankers Book that the actual Balance on Jan 1st, 1902, to the credit of the Fund was £269 7*s* 4*d*, to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 1st 1902.

The balance at the Bank on Dec 31st, 1902, was the sum of £303 2*s* 11*d* I have also checked the receipts for disbursements and find the above account strictly accurate.

January 2nd, 1903.

HENRY A. PITMAN Hon. Auditor

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST

THE South West London Medical Society convened a special meeting to consider the questions that have arisen in consequence of the action of Mr John Troutbeck, coroner for the City of Westminster and the South-Western District, and this was held on Jan 2nd in the drill hall of the 4th Volunteer Battalion East Surrey Regiment, Clapham Junction. The President of the society, Surgeon Major M. Robinson, I M.S , took the chair The proceedings were followed with marked interest by an audience of 83 medical men from the surrounding districts

The PRESIDENT commenced by observing that the novel proceedings of the new coroner in that district called for consideration. The action of Mr Troutbeck in relation to post-mortem examinations had been before the council of the South West London Medical Society and it had been thought advisable to obtain the opinion of counsel concerning Section 21 of the Coroners Act. The London County Council had thought fit to nominate a medical man as pathologist to assist coroners in special cases Mr Troutbeck was the only coroner who, as far as he knew, had to any great extent availed himself of this assistance, but instead of calling in the pathologist appointed by the London County Council in exceptional cases only Mr Troutbeck had made it the rule to utilise the services of the pathologist in question—viz , Dr L Freyberger If a coroner wished to have medical evidence it seemed, according to the Coroners Act, that he should call in the medical attendant on the case and if that gentleman was not available the Act seemed to direct that the coroner should call in some medical practitioner in the neighbourhood. It did not appear that Dr Freyberger had been appointed by the London County Council by advertisement or by competition. No one objected to receive the aid of a pathologist in certain special cases but if a pathologist was called in the medical man in attendance on the case should also be present at the post-mortem examination

The honorary secretary of the society, Dr M MACKINTOSH, then said that in consequence of communications received by him from members of the society, a special meeting of the council was held on Dec. 2nd. Correspondence explaining the matter was laid before the council and in consequence it was deemed necessary to obtain counsel's opinion on Section 21 of the Coroners Act and its subsections For this purpose Mr Hempson, solicitor to the Medical Defence Union, was instructed to obtain the opinion of counsel on the case. This was done and at an adjourned meeting held on Dec. 17th the case as submitted by Mr Hempson and the opinion of Mr M Muir Mackenzie thereon were read to the meeting Counsel was requested to advise (1) as to whether the practice adopted by Mr Troutbeck is in conformity with or in breach of his legal duties as His Majesty's coroner—and if counsel should be of opinion that he is acting in breach of his legal duties, (2) by whom and by what means can he be restrained from continuing thus to act, , (3) generally in the circumstances.

The following is the opinion of Mr Muir Mackenzie —

1 The 21st section of the Coroners Act 1887 confers powers and imposes duties on a coroner If the deceased was attended in his last illness by a medical practitioner the coroner has power to summon the practitioner If the deceased was not attended by a medical practitioner the coroner has power to summon as a witness any legally qualified practitioner who is at the time in actual practice in or near the place where the death happened The coroner further has power by Subsection (2) of the section to direct such " medical witness—that is to say the practitioner who attended the deceased or a practitioner in practice in or near the place where the death happened—to make a post-mortem examination. Then the jury in the events specified in the third subsection have power to require the coroner to summon as a witness some other specified legally qualified practitioner and it is the duty of the coroner to comply with the requisition. Besides having the power to summon the medical witness specified in the enactment it is the duty of the coroner to do so when it is made to appear to him that the circumstances specified in the enactments exist. The words of subsection (1) are may summon," while the words in subsection (3) are shall comply But although the word may in a statute *primâ facie* gives a discretion if the statute in which it occurs is one which relates to public justice and is of general interest and concern the word may" is imperative and imposes a duty See the judgments in Julius *v* Oxford, 5 App Cases and see especially on page 240 and cases there cited My opinion is therefore that the practice adopted by Mr Troutbeck as detailed in the case is not in conformity with the statutory duties imposed on him

2. The enactment does not in my opinion give to any medical practitioner whom the coroner ought to have summoned a right either to bring an action for damages or for an injunction against the coroner to restrain him from summoning Dr Freyberger in future, or a right to apply for a second inquest and mandamus to the coroner to summon him as a witness at a second inquest. If owing to the coroner failing to summon the medical witnesses prescribed in the Act there were to be a miscarriage of justice the court would have power on application to it to quash the verdict and to order a new inquest to be held. See *Re* Mitchelstown 22 L. R. Ireland, 279 Reg *v* Carter" 45 L I 2 B 711 The question in each case whether the court would exercise the power would depend on the circumstances (see R. *v* Coulson " 55/I P 262) The Coroners Act 1887 contains powers for the removal of a coroner by the Lord Chancellor for inability or misbehaviour Further if he is guilty of misbehaviour a coroner may be indicted for a misdemeanour and on conviction be removed See Sections 8 and 35 of the Act. There is also a general power in the High Court to remove a coroner for misbehaviour or misconduct See Jervis on Coroners p 94 and Section 35 of the Act, which preserves the old powers of the court I cannot advise that the conduct of the coroner amounts to misbehaviour which would justify either an indictment of him or an application to the court to remove him If the medical practitioners who in my opinion justly and reasonably complain of the course which the coroner has adopted, desire to proceed in the matter my advice to them is in the first instance to represent the facts to the Lord Chancellor by an influentially signed memorial addressed to him.

Dr MACKINTOSH also read the following letter from Dr S H. Snell —

Glenshee Lodge Wandsworth Common S W ,
Dec. 29th, 1902.

DEAR SIR —I regret that a previous engagement prevents me from being present at the meeting on Friday next About three weeks ago I was called out of bed by the police to a man whom I found to be dead in the shelter near here I of course, carefully noted the circumstances with a view to an inquest I was somewhat surprised to read an account of this inquest later where medical evidence of the cause of death &c. was given by a medical man in no way connected with the case.

Supposing that the coroner prefers his own man to do the post mortem surely the first evidence—namely the circumstances and surroundings &c. should be given by the medical man called in.

If this case bears on the object of the meeting I shall be pleased if you will quote it Yours faithfully

M Mackintosh Esq SIDNEY H. SNELL.

The PRESIDENT said that there were several courses open for them to follow There was the advice of counsel to approach the Lord Chancellor in regard to the conduct of the coroner They could go to the London County Council and do what they could to induce that body to arrange matters with the coroner They could also approach one of the medical protection societies and ask it to take the matter up His view, however, was that in the first instance they had better go to the London County Council

Mr T ARTHUR I. HOWELL (Vice-President of the society) then proposed the following motion —

That this meeting of medical men summoned by the South-West London Medical Society on Jan 2nd 1903 while appreciating the great steps that the London County Council have taken in the interest of public health view with great regret the action taken by the coroner of this district in practically giving all the post-mortem cases to a pathologist selected by the London County Council in direct opposition to the resolution of the Council which declares it is desirable that post-mortem examination in inquest cases of a *special* nature should be intrusted to a specially skilled pathologist."

That this meeting further declares that it would welcome the assistance of a skilled pathologist in suitable cases but protests strongly against the way that this resolution has been interpreted in this district as it has practically superseded the medical attendant in ordinary cases and this meeting respectfully asks the London County Council to give the matter their serious consideration.

He said that the opinion of counsel which had been read practically gave all the facts of the case. The wisest course in a matter of that kind was to go to work in a diplomatic manner and to approach in the first instance the London County Council with the request that it would take steps to see that its recommendation was carried out in the way that it intended and not as the coroner had thought fit to interpret it. From a statement made by Sir William Collins, the chairman of the Public Control Committee, at the meeting of the London County Council on Dec 16th, it appeared that the recommendation approved by the Council was as follows —

That all coroners be informed that in the opinion of the Council it is desirable that post-mortem examinations in inquest cases of a special nature should be intrusted to a specially skilled pathologist

No medical man would fail to avail himself of such assistance because it was not only in the interest of the medical profession but it was also in the public interest that such a course should be followed He contended that that very reasonable recommendation had been carried out in a manner that practically resulted in direct opposition to it. Within the last few months, out of 23 inquest cases in attersea, Dr Freyberger had been called in for 16 cases hey all knew that there could not have been 16 inquest ses of a special nature out of 23. If it were so then attersea must be a most extraordinary place Sir William ollins had also said that "the Public Control Committee did ot contemplate that the medical attendant on the deceased ould be superseded in ordinary cases." Mr Howell, ontinuing, said that he thought the experience in Battersea howed that the ordinary medical attendant had been superseded. His opinion was that they should go first to the ondon County Council with the courteous motion that e had proposed and he was sure they would receive a ympathetic reception They could show the London ounty Council that its recommendation had not been nterpreted in the way that any reasonable man would read t, and then if the Council would not help them they must onsider some other means of dealing with the matter

Dr. L S **McMANUS** said that the coroner, Mr Troutbeck, ad not followed the ordinary ethics of decent society in his lealings with the medical men in that district The attersea borough council had written to the London County ouncil concerning Dr Freyberger and had received an nswer stating that Dr Freyberger had not been appointed athologist to the Council and it was incorrect so to describe im. He concluded by seconding Mr Howell s motion.

Mr W H P **HILL** said that 41, Regent's Park road (the esidence of Dr Freyberger) could not possibly be included n the district of Battersea unless the whole of London was o be absorbed into Battersea. In his opinion the proper man to call in was a medical man from the neighbourhood. Why, he asked, should they have imposed upon them a gentleman who had practically never been heard of before?

Dr. J **MYLES** said that the practitioners had deserved the treatment they had received because they were apathetic and indifferent to their rights.

Mr **LENANE** said that Mr, Troutbeck was the only coroner who had adopted the system complained of. In his opinion the average general practitioner was quite capable of carrying out post-mortem examination in an ordinary case.

Dr **HUGH WOODS** said that the subject had been brought before the council of the London and Counties Medical Protection Society which was of the unanimous opinion that the conduct of Mr Troutbeck was wrong, and the council was ready to take up the rights of the medical practitioners concerned If a medical man was called to a case which afterwards became an inquest case he might find if he were not at the inquest that his character had been damaged. The medical man should be present at the post-mortem examination or duly represented there, otherwise he might be landed in a position disastrous to his practice. He had a right to be present at the post-mortem examination and at the inquest

Mr. E W **ST V RYAN** pointed out that the practice of the coroner accepting mere theories of causes of death framed by a pathologist who had not the advantage of knowing the facts of the case in the same way as an ordinary medical attendant had would sooner or later end in a miscarriage of justice.

Mr J B **HOWELL** suggested that the best course would be to approach the Lord Chancellor.

Mr M. I. **FINUCANE** agreed with the last speaker and pointed out that the coroner was merely a judicial officer under the Lord Chancellor He considered that it was folly to have procured counsel s opinion and then not to act on it.

Mr **JOHN GAY** urged the meeting to accept the motion proposed by Mr Howell because in that way they would get what they wanted by applying to the authority which had issued the instructions to which they objected. The best way was to try the simplest method first.

Dr **BEDFORD FENWICK** advised the meeting to come to some definite conclusion as to who was to be intrusted with the carrying out of the motion if it was passed.

Dr W G **DICKINSON** said that whoever was intrusted with the matter must have definite instructions.

Dr M. G **BIGGS** pointed out that if they were unsuccessful with the London County Council they could then go to the Lord Chancellor

Mr P M. **YEARSLEY** supported the last speaker

The motion was then put to the meeting and duly carried.

On the suggestion of Mr **GAY** it was agreed that the council of the South West London Medical Society should be intrusted with the duty of approaching the London County Council with the resolution and should be empowered to attend with a deputation to explain the circumstances of the case.

The proceedings terminated by the appointment of Mr James B Howell as honorary treasurer for a special fund to be devoted to defraying the expenses incurred in this matter It was hoped that by an appeal in the medical journals the profession generally would help

The meeting ended with a cordial vote of thanks to the President.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

DURING the week ending Dec. 27th, 1902, 6057 births and 4826 deaths were registered in 76 of the largest English towns. The annual rate of mortality in these towns, which had been 19 6 per 1000 in each of the two preceding weeks, declined to 16 9 per 1000 In London the rate of mortality was 16 6 per 1000, while it averaged 17 1 per 1000 in the 75 other large towns. The lowest death rates in these towns were 4 8 in Hornsey, 7 2 in Walthamstow, 8 7 in Hastings, 9 4 in Willesden and in Handsworth, 10 7 in Barrow in Furness, 10 9 in Coventry, and 11 3 in Burton-on Trent, the highest rates were 21 8 in Liverpool and in Rhondda, 22 5 in Hull, 22 9 in West Bromwich, 23 2 in Stockton-on Tees, 23 3 in Reading, 23 4 in Hanley, 24 4 in Bootle, and 26 6 in Merthyr Tydfil The 4826 deaths in these towns included 493 which were referred to the principal infectious diseases, against 563, 593, and 620 in the three preceding weeks, of these 493 deaths 159 resulted from measles, 91 from whooping-cough, 76 from diphtheria, 63 from scarlet fever, 62 from diarrhœa, 31 from "fever" (principally enteric), and 11 from small pox. No death from any of these diseases was registered in Willesden, Hornsey, Bournemouth, Coventry, Warrington, Rochdale, Barrow in-Furness, Huddersfield, Rotherham, Gateshead, or Swansea, while the highest death-rates from these infectious diseases were recorded in Hanley, Burton-on-Trent, West Bromwich, Smethwick, Oldham, Hull, and Newport (Mon.) The greatest proportional mortality from measles occurred in Hastings, West Bromwich, Smethwick, Bolton, Salford, Hull, Tynemouth, and Newport (Mon.), from scarlet fever in Birkenhead, from diphtheria in Hanley, Smethwick, and West Hartlepool, from whooping-cough in Croydon, Tottenham, Northampton, Hanley, Oldham and Cardiff, from 'fever" in Wallasey, and from diarrhœa in Wolverhampton. Of the 11 fatal cases of small pox registered in these towns two belonged to Stockport, two to Bootle, two to Burnley, and one each to Liverpool, Bury, Oldham, Leeds, and Merthyr Tydfil. The number of small pox patients under treatment in the Metropolitan Asylums hospitals which had been 17, 17, and 21 at the end of the three preceding weeks, declined again to 17, no new case was admitted during the week, the numbers admitted during the three preceding weeks having been six, one, and five respectively The number of scarlet fever cases in these hospitals and in the London Fever Hospital, on Saturday, Dec. 27th, was 2528, against numbers declining from 2900 to 2487 on the seven preceding Saturdays, 205 new cases were admitted during the week, against 265, 250, and 279 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 370, 399, and 409 in the three preceding weeks, declined again to 343, and were 165 below the corrected average number *Influenza* was stated as the primary cause of 28 deaths in London, the numbers in the three preceding weeks having been 13, 21, and 37. The causes of 73, or 1 5 per cent., of the deaths registered in the 76 large towns were not certified, either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Salford, Bradford, Leeds and in 40 other smaller towns, the largest proportions of uncertified deaths were registered in Smethwick, Liverpool, St. Helens, Warrington, Preston, Middlesbrough, and South Shields.

In 76 of the largest English towns 9407 births and 5705 deaths were registered during the week ending Jan. 3rd. The annual rate of mortality in these towns, which had been 19 6, 19 6, and 16 9 per 1000 in the three preceding weeks rose again last week to 20 0 per 1000 In London the death-rate was 20 9 per 1000, while it averaged 19 6 in the 75 other large towns. The lowest death rates in these towns were 8 3 in Hornsey 10 3 in Handsworth, 11 6 in Derby, 12 0 in King s Norton, 12 6 in Leyton, 12 9 in Northampton, 13 6 in West Hartlepool, and 14 0 in Middlesbrough, the highest rates were 25 3 in Bootle, 25 5 in Hull, 26 1 in *West Bromwich*, 26 8 *in Oldham*, 27 1 *in Stockport*, in Wigan and in Tynemouth, and 39 4 in Newport (Mon) The 5705 deaths in these towns last week included 603 which were referred to the principal infectious diseases, against 593, 620, and 493 in the three preceding weeks, of these 603 deaths 174 resulted from measles, 123 from whooping cough, 98 from diphtheria, 84 from diarrhœa, 57 from scarlet fever, 55 from "fever" (principally enteric) and 12 from small pox. No death from any of these diseases was registered last week in Hornsey, Wallasey, Halifax, or Stockton on Tees, in the other towns they caused the lowest death rates in Plymouth, Northampton, Nottingham, St. Helens, Gateshead and Newcastle on Tyne, and the highest rates in Hanley, West Bromwich, Stockport, Wigan, Hull, Middlesbrough, and Newport (Mon) The greatest proportional mortality from measles occurred in Hastings, West Bromwich, Salford, Blackburn, Hull, and Newport (Mon), from scarlet fever in Walsall, West Bromwich, and Wigan, from diphtheria in Reading, Hanley, Bury, Oldham and Preston, from whooping cough in *in Willesden and Grimsby*, *from* "*fever*" in *Portsmouth*, and from diarrhœa in Hanley, West Bromwich, and Coventry Four fatal cases of small pox were registered in Stockport, three in Liverpool, and one each in Hanley, Bolton, Huddersfield York, and Merthyr Tydfil, but not one in any other of the 76 large towns The number of small pox cases under treatment in the Metropolitan Asylums hospitals, which had been 17, 21, and 17 at the end of the three preceding weeks, had further declined to 14 at the end of last week, one new case was admitted during the week, against one, five, and none in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday the 3rd inst., was 2378, against 2565, 2487, and 2528 on three preceding Saturdays, 214 new cases were admitted during the week, against 250, 279, and 205 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London which had been 399, 409, and 343 in the three preceding weeks, rose again last week to 415, but were 93 below the corrected average number Influenza was stated to be the primary cause of 37 deaths in London last week, against 21 37, and 28 in the three preceding weeks The causes of 76, or 1 3 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner The causes of all the deaths were certified in Leicester, Nottingham, Salford, Bradford, Leeds, and 44 other smaller towns, the largest proportions of uncertified deaths were registered in Liverpool, Warrington, Blackburn, Halifax, Sheffield, Sunderland, South Shields, and Gateshead

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns the annual rate of mortality, which had been 18 5 19 9 and 21 1 per 1000 in the three preceding weeks, further rose to 21 3 per 1000 during the week ending Saturday, Dec 27th, 1902, and was 4 4 per 1000 above the mean rate during the same period in the 76 large English towns. The death rates in these towns ranged from 17·5 in Aberdeen and 18 3 in Dundee to 23 0 in Glasgow and 23 7 in Paisley The 688 deaths in these towns included 20 from whooping cough, 18 to diarrhœa, six from measles, six from diphtheria, six from "fever," and three from scarlet fever In all, 59 deaths were referred to these principal infectious diseases, against 64, 72, and 68 in the three preceding weeks. These 59 deaths were equal to an annual rate of 1 9 per 1000, which was 0 2 per 1000 above the mean rate from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 16 31, and 32 in the three preceding weeks declined again to 20, of which 16 occurred in Glasgow and two in Dundee The deaths from diarrhœa, which had been 20 and 15 in the two preceding weeks, rose again to 18, and included 11 in Glasgow, three in Aberdeen and two in Edinburgh. The fatal cases of measles, which had been seven and five in the two preceding weeks, rose again to six, of which two occurred in Glasgow, two in Edinburgh, and two in Aberdeen The deaths from diphtheria, which had been nine, nine and four in the three preceding weeks, rose again to six, and included three in Glasgow, where five of the six fatal cases of "fever" also were registered The deaths referred to diseases of the respiratory organs in these towns, *which had* been 133, 141, and 170 in the three preceding weeks, further increased to 193, and were 27 in excess of the number in the corresponding period of last year. The causes of 33, or nearly 5 per cent., of the deaths registered in these eight towns were not certified.

The annual rate of mortality in eight of the principal Scotch towns, which had risen from 18 5 to 21 3 per 1000 in the four preceding weeks, further increased to 21 6 per 1000 during the week ending Jan. 3rd, and was 1 6 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17 0 in Perth and 18 1 in Aberdeen to 23 3 in Glasgow and 27 8 in Greenock The 707 deaths in these towns included 33 which were referred to whooping cough, 14 to diarrhœa, 13 to diphtheria, 10 to measles, four to "fever," and three to scarlet fever, but not one small pox. In all 77 deaths resulted from these principal infectious diseases last week, against 72, 68 and 59 in the three preceding weeks. These 77 deaths were equal to an annual rate of 2 4 per 1000, which was 0 3 per 1000 above the mean *rate last week from the same diseases in the 76 large English* towns The fatal cases of whooping cough, which had been 31, 32, and 20 in the three preceding weeks, rose again last week to 33, of which 26 occurred in Glasgow, four in Edinburgh and two in Dundee The deaths from diarrhœa, which had been 15 and 18 in the two preceding weeks, declined again to 14 last week, and included seven in Glasgow, two in Edinburgh, two in Paisley and two in Leith The fatal cases of diphtheria, which had been four and six in the two preceding weeks, further increased last week to 13, of which four were registered in Glasgow, fou in Edinburgh, two in Dundee, and two in Perth The death from measles, which had been seven, five, and six in th three preceding weeks, further rose to 10 last week and included eight in Aberdeen The fatal cases of "fever," which had been six in each of the two preceding weeks declined last week to four, of which two occurred i Greenock The three deaths from scarlet fever correspondec with the number in the preceding week and included two i Glasgow The deaths referred to diseases of the respirator *organs in these towns* which had been 141, 170, and 193 i the three preceding weeks, declined again last week to 15 and were 34 below the number in the corresponding period c last year The causes of 39, or nearly 6 per cent., of th deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The annual rate of mortality in Dublin during the wee ending Dec 27th, 1902, was 24 6 per 1000, against 25 9, 29 and 30 8 in the three preceding weeks. During the previo 13 weeks the death rate had averaged 27 5 per 1000, t rates during the same period being 17 4 in London a 17 1 in Edinburgh The 179 deaths of persons belongin to Dublin registered during the week under notice showe a decline of 45 upon the number in the preceding wee and included 21 which were referred to the princip infectious diseases, against 16, 22, and 20 in the thr preceding weeks, of these seven resulted from measle four from "fever" four from diarrhœa, three from dip theria, two from scarlet fever, and one from whooping coug These 21 deaths were equal to an annual rate of 2 9 p 1000 the death rate from the same diseases being 1 per 1000 both in London and in Edinburgh. The fatal cas of measles, which had been nine, 10, and nine in the thr preceding weeks, further declined to seven The deat referred to different forms of "fever," which had been thre five, and four in the three preceding weeks, rose again four The fatal cases of diarrhœa, which had been on five, and three in the three preceding weeks, rose aga to four The mortality from both scarlet fever ar diphtheria showed a slight increase upon that recorded recent weeks. The 179 deaths in Dublin includ 30 of children under one year of age and 38 of perso aged upwards of 60 years, the deaths both of infan and of elderly persons showed a a marked decline from t numbers in the preceding week. 12 inquest cases and ni deaths from violence were registered, and 77, or 43 p cent., of the deaths occurred, in public institutions Th ases of 11, or more than 6 per cent, of the deaths were t certified.

The death rate in Dublin, which had been 29 2, 30 8 and 6 per 1000 in the three preceding weeks, rose again to 4 per 1000 during the week ending Jan. 3rd During the st 14 weeks the death rate has averaged 27 6 per 1000 the tes during the same period being 17 7 in London and 17 2 Edinburgh. The 214 deaths of persons belonging to ublin registered during the week under notice showed an cess of 35 over the number in the preceding week, and cluded 23 which were referred to the principal infectious seases, against 22 20 and 21 in the three preceding eeks, of these, nine resulted from measles, four from arlet fever four from diphtheria, three from diarrhœa ro from "fever," and one from whooping cough. These deaths were equal to an annual rate of 3 2 per 1000, e death rates last week from these diseases being 1 in London and 1 8 in Edinburgh. The fatal cases of easles, which had been 10 nine, and seven in the three receding weeks, rose again to nine The deaths from arlet fever, which had been one and two in the two preceding weeks, further increased to four last week. The four tal cases of diphtheria showed a slight increase upon the umber in the preceding week. The deaths from "fever, nich had been five four and four in the three preceding eeks, further declined to two last week. The fatal cases of iarrhœa, which had been five, three, and four in the three receding weeks declined again last week to three The 14 deaths in Dublin last week included 37 of children nder one year of age and 57 of persons aged upwards of 60 ears, the deaths of infants showed a slight increase while hose of elderly persons were more than 50 per cent. in xcess of the number in the preceding week. Five inquest ases and 11 deaths from violence were registered, and 7/ r more than a third, of the deaths occurred in public nstitutions The causes of 17 or nearly 8 per cent. of the leaths in Dublin last week were not certified.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel T B A. Tuckey retires on retired pay Dated Jan. 3rd, 1903. Lieutenant-Colonel Ulick J Bourke retires on retired pay Dated Jan 7th, 1903 Major R. G Thompson retires on retired pay Dated Jan 7th 1903

Captain T H. Goodwin, D S. O, has joined at Woolwich. Lieutenant J C Furness, R A. M C (Militia) assumes medical charge of the 1st Army Corps Staff, Army Pay Department, Fire Brigade, Military Police, Army Chaplains Department, &c Lieutenant-Colonel J Hickman proceeds to Gravesend for duty Captain K M. Cameron joins at Woolwich. Major G Bray has been ordered to join the Western District. Lieutenant F G Richards on arrival in India from South Africa, is posted to the Station Hospital, Poona, for duty Major C S Sparkes proceeds to Aldershot for duty Lieutenant-Colonel W L. Reade assumes medical charge at Weedon vice Major Sparkes.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers) 2nd Middlesex Surgeon Lieutenant D J Duhig resigns his commission Dated Dec 22nd, 1902 1st Newcastle-on Tyne Surgeon Lieutenant G N Wilson resigns his commission. Dated Jan. 7th, 1903

Rifle 4th Volunteer Battalion the Royal Scots (Lothian Regiment) John Tarrat Titterton to be Surgeon Lieutenant Dated Jan 7th, 1903 2nd (Prince of Wales's) Volunteer Battalion the Devonshire Regiment The undermentioned officer resigns his commission —Surgeon-Captain A. R. Rendle. Dated Jan. 7th, 1903. 2nd Volunteer Battalion the East Yorkshire Regiment Surgeon Major A. F A. Fairweather retires under paragraph 111 Volunteer Regulations, with permission to retain his rank and to wear the uniform of the battalion on retirement. Dated Jan. 7th, 1903. 4th (Nottinghamshire) Volunteer Battalion the Sherwood Foresters (Nottinghamshire and Derbyshire Regiment) Surgeon Captain W T Crawford resigns his commission. Dated Jan. 7th, 1903. 6th Volunteer Battalion the Manchester Regiment Surgeon Major R T Sparrow to be Surgeon Lieutenant-Colonel. Dated Jan 7th, 1903. 2nd Volunteer Battalion the Highland Light Infantry The notification which appeared in the *London Gazette* of Dec 19th, 1902, appointing John Freeland Fergus Second Lieutenant, to be cancelled and the following substituted — John Freeland Fergus to be Surgeon Lieutenant. Dated Dec 20th, 1902.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS)

Edinburgh Company David Waterston to be Lieutenant. Dated Jan 7th 1903.

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY

2nd London Surgeon Captain J N Brown from the 5th (West) Middlesex Volunteer Rifle Corps, to be Captain, and to command under paragraph 55A Volunteer Regulations (dated Dec. 23rd, 1902), Surgeon Lieutenant E C Montgomery Smith, from the 5th (West) Middlesex Volunteer Rifle Corps, to be Lieutenant (dated Dec. 23rd, 1902)

THE ARMY MEDICAL SYSTEM

We have received a copy of a little pamphlet on "The Army Medical System, what it is, is not, and ought to be, by One who Knows' It is published by Sands and Co, 12, Burleigh street, Strand, and its price is 1s As will be seen its author does not give his name As it consists of only 90 pages it is easily read through, but it must not be imagined on that account that the limited space given to their consideration affords any indication of the radical changes and reforms in the army medical system which are advocated, for these, if carried out, would altogether reconstruct the medical service. Within the compass of 90 pages the author manages to touch upon or to pass in review, a large number of subjects and he shows very plainly that he is opposed to the present system. He adversely criticises the practice of getting rid of the inefficient soldier as soon as possible by invaliding him. He would have hospitals divided or separate buildings provided for the reception of serious cases of sickness and convalescents and would conduct the former on the lines of a civil hospital officered by the more highly professionally skilled army surgeons He holds that a man cannot be a military man and discharge purely military duties and be at the same time an expert surgeon or physician. The key note of the pamphlet is, we take it, to develop and to exalt everything appertaining to the strictly medical and scientific side of a medical officer's duties and to pay much less heed to those of a purely military nature than as he alleges is now the case. "Until," he says it is realised that it is imperatively necessary to separate the true surgeon or physician from the military man, to separate the soldier nurse from the cook nurse or clerk nurse and to adopt measures to carry out the same no reform really worth having can ever be anything else than a downright failure He summarises his conclusions at the end of his pamphlet under nine heads and urges the taxpayer to study the subject for himself.

RECRUITING FOR THE ARMY

We have for many years past called attention to the defective arrangements existing at our army recruiting depots Some of these are little short of a disgrace So far from these depots being attractive and presenting inducements to young men to enter the service they are far more likely to be repelled by the position of these buildings in some back street or other and by the nature of the accommodation provided inside them. We have always contended that recruiting offices should occupy airy and prominent positions in some of the main streets and not in the slums of a city or town, and that their inside accommodation should be made as attractive, clean and comfortable as possible In fact, everything should be done to maintain, and to increase if possible, the self respect of the intending soldier and to exalt the position of the army in his eyes. It is time that something should be done and we are glad to learn that the subject is at last engaging the attention of the Secretary of State for War

CONCENTRATION CAMPS IN SOUTH AFRICA AND THE PHILIPPINES.

We learn on the authority of the *Army and Navy Gazette* that he concentration camps which have been established in certain provinces of the Philippines by General J F Bell U S. A. have been denounced as furiously as our own concentration camps were in South Africa. It has been proved however and is admitted by the native physicians, that the occupants of these camps have enjoyed a far larger measure of health, comfort, and safety than they would have done in their own homes. Our service contemporary also calls attention to the fact that Dr Lair of the Pasteur Institute of

Paris, as the result of his personal observations, states that these camps in South Africa were clean, comfortable, and well supplied with food and medicines and in some instances were more comfortable than the quarters of the British troops. The Boers themselves freely admitted that the so-called cruelties never had any existence. Dr Lair's report seems to have attracted a good deal of attention in the United States

British National Society for Aid to the Sick and Wounded in War.

The report by this society of its operations in connexion with the Transvaal war of 1899–1902 has just been issued from the offices of the society, 5, York buildings, Adelphi, London, W C It will be remembered that in addition to the work of supplying medical stores and other things necessary for the treatment of the sick and wounded this society sent to South Africa the *Princess of Wales* hospital ship and the *Princess Christian* hospital train. Accounts of both these auxiliaries to the treatment of the wounded are given in the society's report and there is much interesting matter relating to the general working of the society Referring to Dr C W J Chepmell's work in Natal the report says, ' the most notable incident was the able manner in which he organised a bullock transport to Ladysmith in anticipation of the raising of the siege of the place, by which the Red Cross stores were the first to be delivered, and almost immediately after the relief column had arrived in that town "

Retirements in the Army Medical Service in 1903.

Among the retirements which will take place in the Army Medical Service in the course of the present year we notice the names of Surgeon General W S M Price, Surgeon General Sir W D Wilson, K.C M G, Surgeon General G J H Evatt, and Surgeon General T O'Farrell, Colonel J L Notter, Colonel J P Rooney, Colonel J F Supple, C B, and Colonel W McWatters, and Lieutenant-Colonel S H Carter, Lieutenant-Colonel J A Gormley, and Lieutenant Colonel C H Swayne, D S O

Bravery of a Medical Officer.

Captain H C French, R.A.M C, has been awarded the Royal Humane Society's medal for gallantly jumping overboard from the transport *Wakool* in the Straits of Singapore on Nov 17th, 1902, in order to rescue a coloured stoker What made the bravery of the act more conspicuous was that the locality abounded with sharks and that the vessel was at the time going at considerable speed Both Captain French and the stoker were, we are glad to say, afterwards picked up by a lifeboat. Captain French is a son of General French. Another son, Major G A. French, A.S C, obtained the Royal Humane Society's medal by a signal act of heroism some years ago on the West Coast of Africa

Officers' Chargers and Outfits, Quarters and Messes

Special army orders have been issued in regard to provisions for the supply of chargers to officers of the army and the grant of outfit allowance, together with instructions in reference to the furnishing at public expense of officers' quarters and messes at home stations

The Prevention of the Spread of Typhoid Fever.

A report by Professor Koch on the means of combating typhoid fever has just been published by the medical department of the German War Office. Professor Koch, regarding the disease as essentially transferable, lays great stress, among other things, upon the complete isolation of the sick.

Correspondence.

"Audi alteram partem"

THE NEW SYDENHAM SOCIETY'S CLINICAL ATLAS

To the Editors of The Lancet

Sirs,—You have repeatedly accorded to the society which I represent the valuable privilege of addressing its members and others in your pages and I am emboldened by past favours to solicit another The council of the New Sydenham Society is desirous to place before the profession a statement as to what has been done and what is in progress in respect to its great undertaking to publish a Clinical Atlas of medicine, surgery, pathology, and 'all allied branches of professional knowledge The decision to undertake such an atlas was arrived at after much deliberation more than two years ago, and as the first year of its issue is about to be completed we are now in a position which enables us to report as to what is likely to be accomplished.

In the first place the council has had reason to congratulate itself in three several directions The number of subscribers, although much below what it is hoped may be attained, is yet adequate, the cost of the work proves to be much less than was expected, and the supply of material is abundant. In the next place, the council feels that it is due to the society's members to offer some explanation of what may appear like unpunctuality We are only just about to conclude the issue of the series for 1901 and to commence that for 1902 Thus it may be said that we are a twelvemonth behindhand No one, however, who will give the slightest thought to what the production of such a work as this is will feel any surprise at this. Our plates take a long time in passing through the artists' hands and to hurry is to spoil. Many months were consumed in inquiries as to whether the work would receive the support of the profession and it was, of course, impossible to make preparations before a decision was arrived at. We are engaged not in the reproduction of any existing work, but in the publication of an original work of very large dimensions and involving the collection of an immense amount of material, a large part of which now sees the light for the first time

The fact just alluded to must stand as the explanation not only of a certain amount of delay in issue but of some want of systematic arrangement which will become apparent Any attempt at finality in such arrangement would be to the injury of our work. New illustrations may be supplied late which it would be a great pity to exclude and unforeseen impediments may be encountered in the production of any one fasciculus. There is but little room for automatism in the compilation of such a work as ours, and as the foremost aim of those engaged on it will be to make it useful as a clinical record of all that is susceptible of pictorial illustration in reference to disease some latitude must be asked for in the matter of arrangement. We shall do our utmost to study the convenience of the reader but shall not sacrifice his real interests by a too rigid endeavour to adhere to a cut and dried programme. He may now and then encounter supplementary plates, or find a topic which he had thought concluded again referred to It must be remembered, also, in reference to the selection of subjects, that our atlas is an international one and is not intended exclusively for the home profession.

The issue of works for the year 1901 will be completed in a few days by the publication of a double fasciculus illustrating "Xanthelasma and Xanthoma as Symptoms of Functional or Organic Disease of the Liver" When our members for that year receive this fasciculus they will have had for the guinea subscription a printed volume (Von Limbeck's "Treatise on the Clinical Pathology of the Blood," translated by Dr Arthur Latham) and four fasciculi of the Atlas, which contain a total of 22 coloured plates and 21 uncoloured Thus considerably more than was promised has been accomplished, for the council's undertaking did not go beyond the issue of four fasciculi of eight plates each and the addition of a printed volume was only conditional on financial success What makes this result especially satisfactory is the fact that it has been attained on a comparatively small list of members. Now that our year's work is before the profession we may legitimately hope that our list will rapidly increase and if it does so we shall be able to afford much more. Without making any sort of promise I may say that I am sanguine that instead of four we may be able to afford eight fasciculi a year, or their equivalent in an increased number of plates in each If this can be done the Atlas will rapidly develop and will be likely to attract still further additions to our members' list However this may be, it is certain to become by far the largest and most comprehensive work of its class ever attempted

In order to attain the results just alluded to all that is necessary is that our members generally should bestir themselves They have their own interests in their own hands. In the hope of giving a fillip to zeal in this matter the council has decided to accord a small privilege in compensation for trouble taken It will issue to all who pay in one sum the subscriptions of five members for any one year six copies of the fasciculi issued for that year, with also any printed volume that may have been added. This privilege will be accorded not only to local secretaries, but to all members of the profession. As the stones from which the plates are printed will have to be cleaned off almost at once, and no new edition is in the least degree probable, it is desirable that those who wish to secure the work should apply early.

In conclusion, I have but to state that the issue of the Atlas (in its Clinical form) began with the year 1901 and that new subscribers should at once forward their subscriptions for that year and for 1902. If it is wished to save trouble the subscription for 1903 may be added. Our agent is Mr. Lewis, 136, Gower street, W.C.

I am, Sirs, yours faithfully,
JONATHAN HUTCHINSON,
General Secretary (Hon.) to the New Sydenham Society.
Cavendish-square, W.

THE IMPERIAL VACCINATION LEAGUE

To the Editors of THE LANCET

SIRS,—With the majority of my profession I am keenly interested in and have sympathy with the aims of this league, and therefore am concerned with its proceedings which must so intimately affect the social well being of this great nation. As a justice of the peace I have the privilege of seeing a large number of conscientious objectors and of signing the certificates enjoined by a clairvoyant Government that they conscientiously believe that vaccination will be prejudicial to their child's health. I have in consequence exercised much thought upon the question its disastrous results and its remedies. Some crudely and ignorantly dismiss the difficulty by the statement that conscientious objectors are either rogues or fools. This view resolves no part of the problem which has puzzled us all and I join issue with the statement. For although it is true that it is mainly the weak man who causes the trouble and who revels in the unreasoned thought that "he won't be *made*" to submit to the ordeal, still it is sometimes the thoughtful hard headed man, pondering the subject carefully who raises the objection. "If," he argues in effect, "I have my child vaccinated and *my* wife and *myself* revaccinated what do I gain for my trouble? Nothing but a blooming (he would doubtless prefix a still more expressive adjective) sore arm. But if I reject the vaccination what *do* I lose and what do I gain? 1. I *lose* nothing by refusing except a troublesome and possibly an inflamed sore arm. 2. But I *gain* (*a*) If I catch the small pox the benefit of my beneficent neighbours as represented by the urban and rural councils of all descriptions, immediately removing me to a hospital where I am most carefully nursed with every comfort which sickness requires until I am well, while my wife and children, although then compelled to submit to vaccination are well provided for during my enforced absence. (*b*) If on the other hand a member of my family sickens with small pox, the same routine is experienced at the hospital for their welfare, and I receive my wages for doing nothing except keeping out of the way of my neighbours and being vaccinated." The natural sporting instinct of the Englishman helps the reasoning.

How, then, can we be extricated from the dilemma into which our legislators have confined us? If I can appear before a bench of magistrates and express an objection to vaccination (I have never yet heard a case where there was a "conscience" in the matter) and thus obtain a certificate of exemption it is manifest that everyone can do the same, and if this be the case the notion of compulsion is a farce. Would it not, therefore, be honest to admit at once that compulsion in vaccination does not exist? If anyone doubts this let him bring the recalcitrant person before a petty sessions, obtain a conviction and then enforce the fine. I think that he will find the same experience as we underwent in Rugby. The fine was not paid, a "distress" warrant was issued, an auction was the consequence, which speedily degenerated into a storm of rotten eggs and bags of flour, with the auctioneer (obtained from our midland citadel for prudential reasons) leaving the rostrum in a hurry making peace by shaking hands with those nearest to him and the anti vaccination party triumphantly holding the field. Then what is the next step? The law breaker has the best of it, as nothing further can be done. He cannot be imprisoned while he has "goods" on which "distress" can be levied, and yet these cannot be sold to pay the fine while no one will buy. The whole farce requires a Dickens to describe the ignominy into which the law has been brought. It is not statesmanship to hold up the law to ridicule in this fashion when in reality no such thing exists as compulsory vaccination. This being the true position it is quite clear that the law has to be altered, for Englishmen are usually law abiding citizens. How, is the question that concerns us all, for it is imperative that the scourge of small pox should be abated. Without a shadow of a doubt the prevention of all illness is far better in its issue and infinitely less expensive than providing for its treatment.

I would therefore submit the following suggestions for consideration:—1. That the State should publicly abolish—if it can abolish what has already been implicitly abolished by the blind act of our legislators—compulsory vaccination. 2. That the various councils instead of offering a premium upon refusal to be vaccinated and revaccinated, should proceed on the opposite tack and reward those who comply with the annoyance of vaccination, for no one can deny the annoyance. 3. That the State should provide a sufficient supply of pure glycerinated calf lymph for all. 4. That the State should furnish free vaccination to all who desire it. 5. That the State should supply, directly or indirectly hospital accommodation—there would soon be no sufferers to require it—and full wages to all who are afflicted with small pox after efficient vaccination or revaccination (every 10 years if deemed advisable) and to whom a Government certificate should be furnished. But it would be necessary for the State to define what it regarded as efficient vaccination and revaccination. For instance, such a farce as medical men revaccinating in one spot only should be impossible—a case which sometimes occurs at Rugby, where every boy is required to be revaccinated before, or on entering the school. No case should receive the Government certificate under penalty unless four good pocks are manifest and four also from revaccination. 6. In respect of tramps and the "submerged tenth" the grant of a State gratuity to those who obtain the Government certificate would probably cover the difficulty. The cost would be insignificant in comparison with the provision of hospital treatment for sufferers from small pox. 7. Those who still refuse vaccination and revaccination might be left severely alone. This course might inflict some hardship for a time, but nothing like the hardship which at present exists when small pox supervenes. 8. The system of commending or of rewarding those good citizens who submit to vaccination and revaccination would be more efficacious than punishing recusants since the penalty is a dead letter.

It may be argued that the few who would still reject vaccination and who would by their refusal keep small pox alive, would expose the majority to the ravages of the disease. But if vaccination and revaccination be worth anything—and undoubtedly it is absolutely to be depended on when efficiently performed—not one of those who is protected by vaccination, and revaccination periodically conducted, could suffer in consequence. Failing some such scheme as that which I have attempted to outline the vaccination question in this country simply involves the aid of the police or of the military authorities.

I am, Sirs, yours faithfully,
CLEMENT DUKES, M.D., F.R.C.P. Lond.,
J.P. for the County of Warwick.
Rugby, Dec. 31st, 1902.

NOMENCLATURE OF MALARIA: A SUGGESTION

To the Editors of THE LANCET

SIRS,—It would seem that the time has arrived when the diagnosis of cases of malaria must aim at giving the name of the species or variety dealt with and not merely one of the general terms, intermittent or remittent fever as laid down in the last edition of the "Nomenclature of Diseases." Information is wanted as to the geographical distribution of the various kinds of malaria, and this can only be arrived at by recognising them in the new edition of the Nomenclature. The demonstration of the species of malarial parasite which is the infecting agent in a particular case will necessitate the use of the microscope. This routine microscopical examination of the blood will, it may be presumed, bring about a more correct diagnosis of fevers in malarious countries and assist rational treatment. Malta fever was treated until lately with large doses of quinine on the supposition that it was malarial in origin In the same way it is too often assumed that any fever occurring in a malarious locality is malarial in character and quinine is given in enteric fever tuberculosis liver abscess, &c, when a blood examination might have prevented the error The nomenclature I would suggest for the three well recognised species of malaria is the following —

Malarial fever —Synonyms ague intermittent and remittent fever
a Tertian —Synonyms: hæmamœba vivax simple or benign tertian
b Quartan —Synonym hæmamœba Golgii
c. Crescent tertian —Synonyms Laverania laverani æstivo-autumnal fever malignant tertian tropical tertian remittent fever

I have left out the commonly used terms "simple," "benign," "malignant," and "pernicious" as they are misleading The so-called 'simple tertian' may often be more severe than the so-called "malignant tertian.' "Æstivo autumnal" is a term which may apply appropriately enough to the fever as it occurs in Italy, but in other parts of the world is unsuitable The genius of Koch suggested the term ' tropical tertian" for the third variety and this is undoubtedly an excellent name, but as the fever is also found in temperate climates it is also misleading In regard to the scientific names I think Golgi, who discovered that the parasite of malaria consisted of more than one species, should be commemorated, and also Laveran whose epoch making discovery of the malarial parasite has it seems to me, never been sufficiently appreciated in this country In the present edition of the "Nomenclature of Diseases' the old term malarial cachexia has been left out I would propose that in the next edition the chronic form of malaria, when the parasites have disappeared from the blood but the anæmia, pigmentation enlarged spleen, &c, remain, be again given a place, and I would put forward the name Chronic malaria, synonym Malarial cachexia. This short note has been written in order that anyone who takes an interest in this question may have the opportunity of bringing forward other suggestions or criticisms I am, Sirs, yours faithfully,

DAVID BRUCE,
Dec. 20th 1902. Lieutenant Colonel R A M C

RIGHT-HANDEDNESS AND LEFT-BRAINEDNESS

To the Editors of THE LANCET

SIRS —Sir Samuel Wilks in his valuable letter[1] on the above subject shows, I think conclusively that certain practical advantages result from the employment of one hand and arm exclusively for certain movements I do not feel altogether convinced, however, that writing should be included among these. It is true that in writing 'forwards' with the left hand the movements do not correspond with those employed in writing similarly with the right hand, nevertheless, one can learn to write quite well with the left hand and it does not appear to me that any practical disadvantages attach to ambidexterity in the case of writing it is simply a question of learning to write with both hands, and I have known children to show a preference for using the left hand rather than the right for writing I am acquainted with a child who used to write all her home lessons with the left hand, only writing with the right hand when she was compelled to at school. Now through being constantly compelled to write with the right hand, she uses this one almost solely for writing though she can still write fairly well with the left. This child I may remark, is very fond of and not a little skilled in, drawing and she always employs the left hand for this purpose.

These remarks prepare the way for the chief object of my letter, which is to raise the question whether by employing the two hands equally in writing and thus (presumably) the two sides of the brain equally in "word processes' more can be achieved in the realm of language than when one hand only is used for writing If we can secure the development of the motor and sensory speech centres in both halves of the brain instead of one only if that is to say, we can enlarge the anatomical substratum of language, may we not hope to obtain in this way some increase in the capacity for language? This question is capable of being answered by experiment. All that is necessary is to teach a number of children to use both hands equally for writing and to compare their gift of language with that of others who write with the one hand only

I am, Sirs, yours faithfully,
Wimpole street W Dec. 28th 1902. HARRY CAMPBELL

To the Editors of THE LANCET

SIRS,—Sir William Gowers has promulgated in his letter in THE LANCET of Dec 13th a charming theory in the speculation as to the cause of right-handedness But his theory loses much of its weight by being applicable only to those of our ancestors who inhabited the northern hemisphere, suggesting by inference that those south of the equator should all have been left handed by choice Now we know that this is not so and must therefore look for some other reason to account for right-handedness and all that right-handedness involves and includes I would, as opposed to a celestial cause, propound the probability of a very mundane reason. When early man first learned the art of fighting with a weapon, however rude, it would gradually be borne on him that wounds of the right side of the chest were not so fatal as those of the left. Arguing thus he would construct a shield which should be carried on the left arm, leaving the right to wield his weapon and to strike his blow

Kensington-court W, Jan 1st 1903 E A. BARTON

THE HOPELESSNESS OF THE BATTLE AGAINST CONSUMPTION SO LONG AS THE ELEMENTARY SCHOOLS ARE HYGIENICALLY UNREFORMED

To the Editors of THE LANCET

SIRS —A perusal of Mr Felix Clay's criticism in THE LANCET of Dec 20th (p 1722) of my letter of Dec. 6th shows that he has failed to grasp the far reaching effects of sanitary reforms of which hygienic elementary schools is one He points to the cost of the schools and the difficulty of finding a sufficient supply of teachers for so increased a number Moreover, he seems to take it for granted that these reforms can be thrust upon the nation at once in their entirety If this were the case it must be admitted that the difficulties he mentions might arise, but reforms of the nature suggested are a slow growth, and it would doubtless take some years for the beneficent effects of the reforms to become manifest and for the population who under the old *régime* would have died from phthisis to grow up into useful citizens Other difficulties besides that of obtaining teachers arise from the comparative sparseness of the population of the country which is making itself felt in various ways, such as the undermanning of the navy, the imminent conscription and the waning power of colonisation. Is this to be wondered at in a country which placidly allows 60,000 of its most promising, active, and intelligent population to die yearly from a preventable disease? To illustrate this point allow me to take it for granted that the various plans of hygienic reform are in active operation and as successful as their originators could wish and that consumption is eliminated as a common disease almost as completely as leprosy Then the 60 000 English men and women who now die annually in the British Isles from tuberculosis would be saved and added to the number of the wealth producing population In 20 years a number considerably above 1 200 000 which is the figure a multiplication of the former number gives, would be produced As a means however, of representing the increased population this number is unsatisfactory, while it fails completely as an estimate of the increased wealth and health of the country as it does not show the millions of ailing citizens freed from a life of chronic ill health and sickness and the increased healthfulness and energy of the remaining portion of the population Surely it is not unreasonable to suppose that the capital invested in the preservation of child life in the elementary schools and the closing of the various death traps which abound in the kingdom will be amply repaid by the general well being and prosperity of the community and that the cost must be a minor item in the general weal.

Opinions may differ as to the best method of treating a cancer such as tuberculosis affecting the commonwealth may be supposed to be whether the disease ought to be completely eradicated at once by the knife or trifled with by the application of feeble caustics and narcotics. Experience of the latter old wives' method of treatment has taught surgeons to be wary of it. With respect to the argument that the hygienic laws proposed will tend to curtail the liberties of Englishmen, it is quite possible that these changes will be opposed by a sentimental anti progress league which will ultimately, however be brought to its senses when there is a danger of the nation being left behind in the struggle for supremacy by communities more in sympathy with scientific progress and discovery

REFLEXES THEIR RELATION TO DIAGNOSIS IN RHEUMATOID ARTHRITIS

To the Editors of THE LANCET

SIRS,—In Dr R. Llewelyn Jones's interesting paper on the Reflexes in Rheumatoid Arthritis in THE LANCET of Dec. 27th, p. 1746 I notice a reference to "jaw jerks." On his resignation as resident medical officer of the Royal Mineral Water Hospital Bath, Dr Jones kindly showed me this clinical phenomenon which I have carefully tested The mandibular joint being so frequently affected one found plenty of material to work with and it may be of interest to note my conclusions Invariably where the jaw has been recently affected one obtains a smart response to percussion and irritability is so marked that clonus is not a rare occurrence though a single acknowledgment to the tap is more often elicited In cases where the jaw has apparently been free from trouble for many months the jerk is still easily obtained, though in most of these apparently recovered joints grating or slight morning stiffness can be made out. Frequently, however, one meets with cases giving histories of former jaw attacks and where no evidence of any active arthritic mischief is present I have received a response, showing how persistent the irritability is. An interesting case recently in hospital gave no history beyond that of aching teeth and on examination though no dental caries was made out yet the jaw responded. The aching teeth, I take it, was a referred joint affection. In most cases, however, where jaw trouble has been complained of the molars and bicuspids were degenerate or absent, though the incisors seemed to be peculiarly resistant.

A passing reference to knee jerks is not out of place. We notice here in rheumatoid affections of the lower extremities where no joint contractures have occurred a more than slight increase in deep reflexes In fact digital percussion to the patellar ligament not infrequently throws the affected leg into an almost epileptiform condition of clonus, and this seemingly often out of proportion to the joint changes. As a rule, where such a state of affairs exists the other limb partakes in excitability though not necessarily to the same extent. In one case I am thinking of Dr Carter pointed out to me the markedly spastic gait of the man. Here Babinski's sign was absent.

The most marked condition of 'myotatic irritability I have seen was in a middle-aged woman who was greatly distressed one morning by an attack of clonic muscular spasms of all the extremities especially the left side. Her muscular convulsions shook the bed and on firmly holding the arm or leg muscles rapid twitchings were to be felt. Her pulse was 160 the respirations were 40 and the temperature was 99 6° F On her admission we noticed Stellwag's symptom occurring rhythmically in both eyes slight proptosis, and von Graefe's sign. There was no thyroid enlargement and her morning pulse was 80 Belladonna, bromide, and digitalis seemed to cut the attack short. Some might quote hysteria as the cause, but her general behaviour was against it and I believe that the arthritis was closely connected with the attack—probably of the same origin.

I am Sirs yours faithfully

J W MALIM B A. M.B B C Cantab

Resident Medical Officer Royal Mineral Water Hospital Bath

Bath Jan. 3rd, 1903.

To the Editors of THE LANCET

SIRS,—I have read Dr R. Llewelyn Jones's paper under the above title in THE LANCET of Dec. 27th p 1746 with a great amount of interest, but I should like to draw attention to a statement he makes which I cannot allow to pass as correctly representing my views as to the origin of the disease. On page 1748 he says "Dr Bannatyne ascribes the disease to a toxæmia affecting the anterior cornua of the cord.' Now this is not my idea of the origin of the disease. To put it shortly, I look on rheumatoid arthritis as due to specific bacteria having their nidus in the affected joints themselves and that the joint symptoms are the primary and essential symptoms of the disease. I look on the vaso-motor and other nerve symptoms as purely secondary, possibly caused by absorption of the bacterial products elaborated by the micro-organisms in the joints My principal point is that I look on the joint troubles as caused by the local action of the bacteria and not as the result of trophic changes due to a toxæmic poisoning —I am Sirs, yours faithfully,

GILBERT A. BANNATYNE, M D Glasg

Bath Dec. 28th 1902.

PERMANGANATE OF POTASSIUM IN SNAKE-BITE

To the Editors of THE LANCET

SIRS,—In regard to the annotation respecting the efficacy of the subcutaneous injection of solution of permanganate of potassium referred to in THE LANCET of Dec. 20th, p 1711, it was strikingly illustrated by experiments conducted by M Louis Peringuey and myself with the poison of the puff adder and described in the *Medical Press and Circular* for June 1886 Since then with great caution, I have employed the same remedy likewise subcutaneously injected, in a very extreme case of blood poisoning occurring in a man who in order to remove an obstruction in a drain pipe had pushed his arm into it thereby receiving a scratch, after which the whole arm gradually swelled up to an enormous size In this condition attended with severe constitutional symptoms threatening imminent death, he came to me. All hope seemed gone but he made a complete recovery A few notes of this case, which occurred in 1894, I recorded in the *British Medical Journal.*

In the snake-bitten dog although I used a strong solution and injected it freely into the tissues and also into the muscles there was only a small local reaction. The animal made an astonishing recovery and it was well bitten several times over by the very same snake which had caused the death of another dog within about six hours. There were scarcely any noticeable dangerous symptoms except a little listlessness and sleepiness. The remedy probably destroyed the virus. The injection of the solution did no harm and the dog scarcely suffered at all. The treatment should only be used in dangerous cases in human beings and always with much care and, as a rule, only in snake-poisoning should intra muscular injections be made.

I am, Sirs, yours faithfully,

Grimsby Dec. 24th 1902. GEORGE GRESSWELL.

THE STAFFING OF RECEPTION HOUSES

To the Editors of THE LANCET

SIRS —The London County Council with its habitual progressive spirit in lunacy matters having decided to establish reception houses for incipient mental disorders, it is very essential that these should be staffed from the outset in the most efficient manner The treatment of incipient mental disorder has occupied my attention for many years past and I trust therefore I may not be considered as presuming in venturing to express my views in this particular to which I have also given very considerable attention Many members of our own profession are in the habit of asserting that no special skill or experience is needed in the treatment of mental disorder This view, I consider is the strongest and most conclusive evidence that could be advanced that they know absolutely nothing of the subject.

An alienist physician of the present day must not only have a full and long experience of mental disease but he must be a specialist in neurology, gynæcology ophthalmology, and in fact in every specialism, to the extent of knowing when he needs the aid of one of these specialties The asylum physician, it must be remembered, has unequalled opportunities in the large institutions for the insane for observing not only mental disease, but every other form of disease over lengthened periods and under conditions of which he has absolute control No other physician has equal opportunities for observing and treating disease generally The profession at large has had little instruction in mental disease and consequently is too often prone to treat cases of ephemeral epi phenomenal mental disorder as if it were a grave mental attack and to imagine that all patients will recover without special treatment as easily as these Alienists, however could bear testimony, if it were needed, to the frequent unsatisfactory ending of such unskilled and too often unscientific treatment. Very much more might be said on this subject but it is a distasteful one to touch on

The scheme for staffing such an institution as that under discussion which I would suggest is a resident physician, who should have had considerable experience in mental diseases, either as superintendent or senior medical officer of an asylum, with junior residents, who should be qualifying for posts in asylums The experience of the junior posts would be the best possible introduction to alienist work and every alienist physician should if possible, begin with work in reception houses This would in time add materially to the value of the asylum staff and would reflect later on the reception house. The reception house physician should have power to call in specialists of every kind whenever necessary and he should have also the power of consultation not only in treatment of individual cases, but in matters of organisation &c., with an alienist physician. Such consultant physicians might well be retired asylum superintendents, many of whom although no longer equal to the duties of superintending a large asylum of 2000 beds would be quite equal to, and of the greatest value to the public in such work

In conclusion, I would repeat that although the bodily conditions are of great importance in the early stages of disorder the mental side is of still greater, and that unless both sides are attended to the favourable result of the reception house treatment may not only be impaired but destroyed

H RAYNER, M D Aberd

Queen Anne street W Jan 1st 1903

THE BRANCH MEDICAL COUNCIL FOR IRELAND

To the Editors of THE LANCET

SIRS,—Will you be so good as to permit me to state through the medium of THE LANCET that in conformity with the following resolution of the Branch Medical Council for Ireland passed on June 2nd 1902 I have terminated my connexion with the Irish Medical Registration Office —

> That in order to carry out the requirements as to economy in the management of the Irish Branch Council notice be given to the landlord of the premises that the office will be surrendered on 31st December next or as soon after as may be and that notice of the terminations of their appointments at the same date be given to the registrar of the branch and to his clerk

I am, Sirs, yours faithfully,
Dublin Jan 5th 1903 S WESLEY WILSON

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST

To the Editors of THE LANCET

SIRS,—From a legal point of view one may reasonably inquire whether Mr Coroner Troutbeck has the power to pass over a medical practitioner who has attended the deceased at death or in the last illness, and from the authorities I have consulted it would appear not. Further on reading the Coroners Act it seems that the intent thereof is that the attending medical man, or one called in at the death, should be summoned by the coroner and directed to perform any post-mortem examination, except by implication in the particular case provided for in the second part of Section 21 From all one knows of Mr Troutbeck s action of late he appears to ignore these sections of "the Act of Parliament" and to regulate his procedure on some "pious opinion ' of the Public Control Committee of the London County Council

It will be observed that even this "pious opinion" of the County Council only refers to inquests of a "special nature" and says nothing of its being adopted in the generally sweeping way which Mr Coroner Troutbeck has been doing The fact is that the present method of appointing coroners by county councils and exacting from candidates "agreements to give effect to fads and crotchets of county councillors ties the hands of coroners and converts their courts from what should be strictly legal tribunals, carrying great weight, into inquiries to which most people give little attention and the proceedings and records of which often cause great ridicule and corresponding contempt It is admitted that the Government has as yet made no alteration in the law of coroners and yet the County Council would override the Act of Parliament by exacting pledges from candidates to go outside the procedure laid down by such Act

It requires, in my opinion simply cohesion and determination on the part of medical men to bring both the County Council and coroners to a sense of the illegality and wrong done, both from a legal and medical point of view, by this new procedure

I am, Sirs, yours faithfully,
Dec 29th 1902 MIDDLE TEMPLE

BIRMINGHAM

(*FROM OUR OWN CORRESPONDENT*)

Family Clubs

CONSIDERABLE agitation has been aroused in Walsall by the combined decision of the medical practitioners there to give up this form of the club system on Feb 1st. This decision will affect also a large portion of the population in the Midland districts The particular evil complained of in this private club system is that of employing a collector who canvasses for members at the rate of 1*d* per week and exacts a large percentage, as much as 25 per cent , for his share of the work of introduction The responsibility is then left to the medical practitioner to deal with and to attend them. This pernicious and eminently commercial plan inevitably leads to touting in its worst form and is degrading to the character and dignity of the profession. The action of the medical profession is not only in accordance with right traditions but also with the progress of the age. This determination refers only to this form of club and does not affect the ordinary friendly societies whose business is conducted on legitimate and proper professional lines.

Christmas at the Hospitals

The decorations of the various hospitals of Birmingham this year and the entertainments given to the patients and visitors have been quite up to the usual high standard of excellence Infinite pains have been taken in the execution of the details of this work to make the institutions bright and cheerful for the inmates The General Hospital occupied two evenings with the performances given by the resident medical officers and the nursing staff Much enthusiasm and energy were also exhibited at the Queen's Hospital in the efforts to make the season as comfortable and happy as possible for the large number of inmates

Female Ambulance Corps

Attention has been called to the fact that, with all its reputation for progress Birmingham has no organised band of ambulance women Good work has been done individually by attendance at classes and qualifying for certificates in ambulance work. Last year, in various quarters of the town and neighbourhood as many as 284 women became proficient in first aid, but no coöperation exists nor is there any combination to utilise their services publicly A division of ambulance women would no doubt be of much importance for there are many cases of accident or illness where the help of women would be of the utmost advantage It is true that in some of the large factories there are women who have passed the necessary examinations and are well qualified to act, but the requirement for their services is limited to the works in which they are employed It is estimated that there are about 900 women in Birmingham able to give first aid and it has been considered that from among them a well equipped division might be formed. Their attendance at public gatherings in the parks recreation grounds, and at certain stations might often lead to their services being called for and to pain and suffering being avoided by their ready and intelligent help. The suggestion is a good one and if the plan were carried out efficiently and worked under systematic control it would serve an admirable purpose.

The Dangers of Acetylene

It may not generally be known how much danger may exist in the use of acetylene for even toy purposes owing no doubt, to the want of a proper understanding of its manipulation and use A lamentable accident occurred recently to a youth, aged 16 years, who essayed to light the lamp of his magic lantern with acetylene gas Having provided some calcium carbide he sought to use it in accordance with instructions gathered from sundry papers and journals In the course of these efforts there was a loud explosion and the boy was burnt so much that he died subsequently from the injuries received—which shows once more that a little learning is a dangerous thing, more especially in dealing with substances of such potency as those used by this unfortunate youth.

Hospital Sunday Fund

The total receipts this year amounted to £5014 13*s* 5*d* The expenses were slightly less than those of last year—viz , £288 7*s*. 5*d* The balance has been apportioned among various institutions interested.

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Infirmary Question.

AT the meeting of the Manchester Infirmary board held on Dec 29th a report was received from the medical board in which the following opinions were unanimously expressed ' That it is undesirable to have an out-patients' department away from the hospital , that an accident and urgency department should be established in the town , that such accident department should contain 20 beds , that it is advisable that the accident and urgency department be placed in a central and prominent position , that members of the honorary medical and surgical staff be appointed to superintend the working of the emergency department , that a mortuary provided by the town be attached to the buildings " The chairman Mr John Thomson said that the report was an answer to questions which they had asked the medical board and that they were not committed to it. A member stated that though agreeing with it as a whole the probabilities were that more than 20 beds were required. The report was not further discussed.

Joint Hospital Scheme

On Dec. 22nd a conference convened by the Local Government Board on the joint hospital question at Bury was concluded. Dr G S Buchanan, medical inspector to the Local Government Board, presided It was agreed that a new authority should be formed consisting of the borough of Bury Radcliffe Whitefield Ramsbottom, Tottington, and the Bury rural district to deal with small pox and other infectious diseases. The inspector recommended, and it was agreed that pending the issue of a provisional order mutual arrangements should be made forthwith at Ainsworth.

Diet for an Infant aged Two Years

A case which it may be worth while to notice as we are supposed to be on the eve of important developments of education both ' voluntary and "provided occurred the other day at Salford It is only one of thousands like it all over the country showing how useless in some directions at least, is the equipment for the needs and duties of life brought away from the elementary schools At an inquest on the body of a child two years old held on Dec 23rd the mother said that she fed him on bread, cheese, and beer because he asked for them. The wives of canal boatmen are not those from whom to expect advanced views as to infant feeding, but it is not creditable to our system of education—all-embracing as it is—that women should be found so grossly ignorant as this woman. The coroner said that he should report the case to the National Society for the Prevention of Cruelty to Children, but surely she is not the only one to be blamed. The diet will have prepared your readers for the verdict of the jury—"Death from convulsions caused by improper feeding "

Jan 5th

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT)

The Outbreak of Small pox in Liverpool

LIVERPOOL is being visited by a severe outbreak of small-pox, yet the public mind seems little perturbed A large seaport like Liverpool is always exposed to attack by zymotic disease, which may be imported on shipboard from any quarter of the globe. In the case of bubonic plague the ports of origin are easily determined, when effectual supervision can be exercised, but the case is otherwise with small pox. Until last year Liverpool had enjoyed a lengthened respite from the disease and the excellent sanitary arrangements of the city inspired the hope that cases would be few and far between Now the disease is rife in the city During the last week of 1902 there were 74 fresh cases, and on Dec 31st 26 additional cases were notified to the health authority, making upwards of 206 cases under treatment in hospital. The fact of 50 fresh cases having been reported within the past seven days calls for precautionary measures of an effective character Revaccination is being strongly urged by the medical officer of health. Unfortunately, people in the first stage of the disease are moving about the city, carrying the germs of the disease with them in offices, tramcars, shops &c. so that the energies of the health department will have to be exercised to their fullest extent One of the Local Government Board inspectors on his recent visit to the Liverpool Workhouse had suggested to the committee that, in view of the number of cases of small pox, greater precautions should be observed in the matter of visiting, which should be restricted to the narrowest possible limit. Within a fortnight four cases had been removed from the workhouse to the small pox hospital At the last meeting of the workhouse committee it was stated that on the previous day the Lancashire Asylums Board had paid a visit to the Whittingham Asylum and the medical superintendent there (Dr J F Gemmel) declared that he would accept no more insane cases from any area in Lancashire infected by small pox. This resolution was arrived at despite the protests of the Liverpool members of the asylum board. This decision would apply to Oldham and Burnley as well as to Liverpool. In this connexion it may serve a good purpose to draw the attention of the tramways committee of the city council to the disgraceful overcrowding of the electric cars. These cars are registered to seat 22 persons inside and it is no uncommon thing to find 10 or 12 persons over and above the recognised number crowding the inside of the car, thereby preventing the admission of fresh air The atmosphere is sometimes positively sickening, and at a time when small pox, measles and scarlet fever are rife in the city this practice ought not to be permitted. At certain hours of the day extra cars might be put on, which would materially assist in preventing overcrowding

The Liverpool School of Tropical Medicine The Discovery of the New Parasite in the Gambia &c

A report has been received by the honorary secretary of the School of Tropical Medicine from Dr J E Dutton and Dr Todd the members of the tenth expedition of the school which has been despatched to Gambia and French Senegal for the special purpose of studying the new parasite, which Dr Dutton only recently discovered in a patient under the care of Dr Ford, the colonial surgeon of the Gambia. Their report is very interesting and shows that they have found the parasite again in a European and in several natives. The parasite has some resemblance to the tsetse fly which causes such ravages among cattle in South Africa. Fortunately, it is not so fatal to man It produces a continuous feeling of illness, with occasional attacks of fever The researches of the expedition are of the greatest importance, as it is likely that many of the cases of West African fevers are really due to this new germ. The expedition at present on the Gold Coast is, among other matters, studying the tsetse fly

Dr Logan Taylor writes under date of Dec 11th that he has procured a horse suffering from the disease It appears that there are only two horses at present on the Gold Coast and it is to one of these that Dr Taylor refers He has been instructed to investigate on the Gold Coast the subject of the new parasite in man discovered in the Gambia.

St Helens Hospital Extension Generous Donation.

An anonymous donor, who simply calls himself "A Former Resident and Manufacturer in the Town," has sent a donation of £1000 to the St Helens Hospital extension fund.

Birkenhead Borough Hospital

Rather more than 12 months ago an additional ward was added to the Birkenhead Borough Hospital and a home for the accommodation of nurses is now in course of erection These additions and the ordinary cost of the maintenance of the hospital necessitated an increase in the annual income of the charity of £550 In response to appeals which have been made by the committee a little more than £300 has been subscribed by way of addition to the subscription list. The working men of Birkenhead recognised the benefits of the hospital by subscribing £1152 last year Mr E K Laird, the president of the hospital has issued a strong appeal to the Birkenhead public to emulate the praiseworthy efforts of the working men of the borough

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

The Royal Victoria Infirmary Newcastle on Tyne

THE building of the Royal Victoria Infirmary is now being rapidly proceeded with There are about 350 workmen engaged and as most if not all of the foundations are already laid the progress is much more apparent than it has hitherto been. The nurses' home which occupies one corner of the ground, is already built to the third storey and will be completed first The nurses are domiciled at present in homes throughout the city which is found to be somewhat inconvenient, hence the reason for pushing on the building of this part of the infirmary so rapidly

New Lectureship on Ophthalmology at the College of Medicine Newcastle on Tyne

On account of the report of the representatives of the General Medical Council of their recent inspection of the final examinations it has been decided by the council of the College of Medicine to institute a lectureship in ophthalmology Hitherto these lectures have been most ably given by the professor of surgery, but as the representatives consider not only that they should be separate but that there should be a separate examination in ophthalmology for the B S degree, the council of the College of Medicine has decided to fall in with the recommendation

The Durham College of Medicine Gazette

This journal, the publication of which was commenced about two years ago under the lengthy title of *University of Durham College of Medicine Gazette, for Graduates and Undergraduates of the University of Durham College of Medicine* has proved a great success The profit for the two years' working shows a surplus of £147 The journal consists principally of a leading article on some popular medical or surgical subject two or three pages of "notes on current topics, a clinical lecture delivered at the Royal Infirmary, several minor articles, three or four pages on athletics and occasionally a poetical effusion Any graduate of Durham who is not a subscriber will be well repaid by sending 2*s* 6*d* the annual subscription, to the honorary treasurer *College of Medicine Gazette*, Royal Infirmary, Newcastle.

Northumberland and Newcastle Medical Association

Following the appointment of a judicial committee to adjudicate in cases of offences committed by practitioners against the objects of the Northumberland and Newcastle Medical Association and the County of Durham Medical Union new rules have had to be added to the present standing rules of the two societies to regulate the appointment of the judicial committee and to give them power whereby to act. Considerable benefit is already being felt from the appointment of this committee, because several miners associations already see how serious it would be if they were unable to secure the services of a proper consultant in cases where they desired one.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS.)

Small pox

SWANSEA has been free from small pox for several weeks. During the third quarter of 1902 there were 96 cases of the disease in the borough and 15 terminated fatally There were 706 "contacts" kept under observation and all over 10 years of age were offered vaccination or revaccination. Only 96 of these persons refused to be vaccinated and 16 of them were attacked with small pox. In the Newport (Mon.) Hospital there are six cases of small pox and a steward engaged on a Spanish ship, which arrived in Cardiff from Bilbao was admitted to the Cardiff Small pox Hospital on Dec. 27th

Rhymney Cottage Hospital

The medical service in connexion with the Rhymney collieries and ironworks is under the control of a committee by which a fixed salary is paid to the surgeons employed. This committee has now set about the establishment of a cottage hospital and the foundation stones of the institution were laid on Dec 27th The site together with a donation of £100 has been given by the Rhymney Iron Company, but nearly the whole of the remaining cost of the building estimated at £2285, together with the maintenance of the hospital, will be defrayed by the workmen The hospital will contain two wards, each having accommodation for four patients, a receiving room an operating room, a committee room, a matron s room, a nurses sitting room, kitchens, and three bedrooms

Measles at Newport

A very severe epidemic of measles is prevailing in Newport (Mon)—so severe, indeed that it has been deemed advisable to postpone the hospital balls and the new year's dinner and treat to poor children. The Sunday schools are closed and the day schools will not reopen after the holidays for a few weeks

South Devon and East Cornwall Hospital

As a result of the recent Hospital Saturday collections in Plymouth the sum of £550 has been forwarded to the treasurer of the South Devon and East Cornwall Hospital Plymouth. The total sum received by the hospital from the Hospital Sunday collections on Oct. 26th last is £794

Memorial to a Medical Man

A memorial fountain has been erected in Beechwood Park, Newport (Mon), to the memory of Dr John F L. Mullin who died on Feb 17th, 1902, aged 52 years The inscription on the fountain contains the words "The Poor Man's Friend "

Jan 6th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Physicians of Ireland

IT is announced that the seventh award of the triennial Reuben Harvey memorial prize will be made on July 1st, 1903 The prize may be competed for by all students of the various schools of medicine in Dublin and also by graduates or licentiates of these bodies of not more than three years' standing at the time of the award The prize, value £25, will be awarded to the writer of the best essay on Animal Physiology and Pathology The essays, bearing fictitious signatures, are to be lodged with the registrar of the Royal College of Physicians of Ireland Kildare street, Dublin, on or before June 1st, 1903

Epidemic Disease in Dublin.

While the council of the Dublin Corporation has been quarrelling about the site of the proposed isolation hospital what everyone anticipated has occurred. About three weeks ago an epidemic of typhoid fever appeared in Church street and six patients were transferred from there to Cork street Fever Hospital. When, on Dec. 24th a second case of small-pox was discovered in Dublin the authorities at the Cork-street Hospital were unable to find accommodation for it and it was accordingly transferred to the Hardwicke Hospital and, after much difficulty, admitted there. Sir Charles Cameron wrote to the Lord Mayor to remind him that the latter hospital is situated in a congested district of the city and in the immediate vicinity of several large public institutions A meeting of the corporation was held on Jan. 5th in the Council Chamber, Cork hill, when Sir Thomas Pile speaking on behalf of the public health committee, said that they should now throw the whole responsibility in this matter on the corporation The condition of things is most serious on account of the fact that there are at present 236 cases of small pox in Liverpool—100 cases having appeared during the last ten days—while the proximity of Liverpool to Dublin and the number of persons coming backward and forward renders it very probable that an epidemic of that disease would soon break out in this city Sir Thomas Pile said that he was authorised by the medical staff to say that in their opinion it was almost impossible to prevent an outbreak in Dublin during the present year Sir Thomas Pile then moved—' without going into the vexed question as to the site —that the public health committee should be directed to secure an isolation hospital immediately, the cost not to exceed £3000 After some discussion this motion was carried, the question of the site being left to the committee

The Belfast Maternity Hospital

The annual sale of work for this charity was held just before Christmas, when Mr H. H. McNeile, D L., occupied the chair and the bazaar was opened by Mrs Theodore Richardson

Christmas at the Belfast Hospitals

At the various hospitals in Belfast Christmas was spent in the usual happy way an effort being made on all sides to render it bright and cheery for the sufferers This was particularly the case at the two children s hospitals, where there were beautiful trees laden for the little patients

Queen s College, Belfast

The numerous old pupils of Professor Meissner Ph.D , who since 1865 has held the chair of Modern Languages, will regret to hear of his retirement under the Treasury age rules. He is a profound scholar and as librarian of the college has proved himself a cyclopædia of knowledge.

Health of Belfast

During the period embraced between Nov 16th and Dec 13th 275 cases of zymotic disease have been notified—viz., 85 cases of typhoid fever, 54 cases of scarlet fever 60 cases of erysipelas 44 cases of simple continued fever 34 cases of diphtheria five cases of puerperal fever, and three cases of membranous croup The death-rate was 26 7, being 5 4 from zymotic diseases and 8 8 from chest affections. Although the number of cases of zymotic disease notified are fewer than in the last report presented by the officer of health to the corporation, yet the deaths are more numerous, a fact accounted for by the great increase in the number of deaths from measles, which disease seems to be epidemic in some districts of the city Typhoid fever and scarlet fever appear to be decreasing

The Belfast Medical School

Lectures at Queen's College and clinics at the Royal Victoria Hospital began again, after the Christmas recess on Jan. 6th

Jan. 6th.

PARIS

(FROM OUR OWN CORRESPONDENT.)

An Information Bureau for Medical Men

DR. R BLONDEL the general secretary of the Medical Press Association has managed to inaugurate a scheme which will prove of great service to foreign medical men and medical students. It takes the form of a bureau where information may be obtained as to Paris medical life and such matters as hygiene water supply and the like I shall give your readers full details of the scheme next week.

The Re organisation of the Hospitals

The Municipal Council has already ear marked the sum of 40,000,000 francs, which sum has been handed over as a loan for the relief of the pressing necessities of the Assistance Publique The total sum really required was 120 000 000 francs, so that it has been found necessary to revise the original estimates The sum allotted for rebuilding the Pitié Hospital, a portion of which is in ruins, is 6 000,000 francs and the new hospital will be built on some land belonging to the Salpêtrière. It will contain between 700 and 800 beds The hospital for contagious disease, which has up to the present consisted of temporary buildings at Aubervilliers, will be rebuilt at Ivry It is to cost 3,500,000 francs will have 500 beds, and will be built in 14 separate blocks, completely isolated one from the other The new Beaujon Hospital is to be built on the right bank of the Seine on land which has been cleared by the demolition of some fortifications. It will contain 1000 beds and will also be built on the separate system One block will be reserved for tuberculous cases This hospital will serve as an infirmary for senile and chronic cases and is estimated to cost 3,000,000 francs The Broussais Hospital will be rebuilt on its present site. It will contain 500 beds and is estimated to cost 4,000,000 francs. On the left bank of the Seine will be erected a large hospital containing 1000 beds which will take the place of the present Laennec and the Charité hospitals The Saint Antoine Hospital will have an addition of a new block to contain 500 beds The land which lies between the Cochin and the Ricord Hospitals will be bought and on the combined sites will be built a large hospital containing 1000 beds. The asylums for the aged—namely, those of La Rochefoucauld and of Brévannes—will be increased, the one by 200 beds and the other by 700 beds. A sum of 1 500,000 francs is apportioned for bedding and linen of which the Assistance Publique stands in sore need The result of these works will be an addition to the resources of the Assistance of 1916 hospital beds and of 900 infirmary beds These will necessitate an annual sum of 2,000 000 francs for upkeep M. Ambroise Rendu, the municipal councillor in charge of the report on the condition of the Assistance Publique, expresses a hope that both the Government and the departmental treasuries will make grants in aid of the Paris hospitals, for more than half the patients treated in the Paris hospitals come from the provinces The director of the Assistance Publique has issued a statistical paper showing the absolute necessity for a further supply of beds. The total number at present at the disposal of the Assistance is 7497 and in times of stress extra beds have to be put up in the wards, the number varying from 1704 at the end of February last to 504 at the end of June last.

New Laboratories at the Hospitals for X ray Work.

Up to last year there were only three laboratories for x ray work in all the Paris hospitals. At the end of the year, however, the council of the Assistance Publique issued a recommendation that x ray laboratories should be started in 20 of the hospitals which are under the Assistance. The Director General therefore nominated a committee to report on the matter but this committee unfortunately was unable to come to a decision. This was a misfortune, for the x ray service as it used to be was quite insufficient. For instance, supposing that the surgeon to the Hôtel Dieu saw a patient who had been admitted during the night and who was too ill to be moved If the surgeon wished to examine the patient by the x rays he had to send a requisition to the x ray laboratory at the Salpêtrière Hospital. The director of this laboratory then had to take all the necessary apparatus to the Hôtel Dieu and to make the examination Then he had to go back to the Salpêtrière Hospital to develop his plate and to print proofs and send them to the surgeon All this time the patient was kept waiting The Society of Hospital Medical Officers was much disturbed by this state of matters and at its meeting on Dec. 19th the following resolutions were unanimously carried —

1 Every hospital should be provided with an x ray department 2. This department should include a room fitted with photographic accessories more especially a dark room for development 3 The management of the x ray department should be, subject to the control of the physicians and surgeons in charge of a young medical

man possessing expert knowledge as well as medical and surgical experience The post should preferably be given to an *interne* or to a former *interne* and should be thrown open to competition He should have one or more nurses as assistants and to these nurses should be given the duty of keeping the apparatus in order and of looking after what may be called the photographic *cuisine* 4 With a view to keep down expenses as far as possible radioscopy should be used in preference to radiography in every case in which it seems that a diagnosis can be made without the use of the latter and only the really poor should be allowed an x ray photograph for nothing

It is much to be hoped that the Municipal Council will fall in with these recommendations

BERLIN

(FROM OUR OWN CORRESPONDENT)

Syphilitic New Growth of the Stomach.

PROFESSOR EINHORN of New York has published in the *Münchener Medicinische Wochenschrift* an account of a syphilitic growth of the stomach occurring in a man, 42 years of age The patient had contracted syphilis 12 years ago and had complained of gastric troubles for seven years, but his weight had decreased by only eight pounds during that time A growth having a nodular surface and measuring about five centimetres in length and two centimetres in breadth could be felt in the epigastric region The stomach lay immediately under the growth and reached below the umbilicus. Chemical examination of the contents of the stomach showed the presence of free hydrochloric acid one hour after a test breakfast and there was no residual chyme left in the stomach from the previous day The case at first appeared to be cancer, but owing to the circumstances that the disease had been in progress for seven years, that the patient's loss of weight had been relatively small and that free hydrochloric acid was present, the diagnosis of cancer became rather uncertain. Under anti syphilitic treatment, consisting in mercurial inunctions and the administration of potassium iodide, the growth disappeared in less than six weeks. The patient's weight once more increased and within three months he was free from gastric troubles Professor Einhorn says that the differential diagnosis between cancer and syphilis in such cases is not easy and that the nature of the lesion is proved only by the success of anti syphilitic treatment

Death of Professor Schede

Dr Max Schede ordinary professor of surgery at the University of Bonn and director of the University surgical clinic, died at Bonn on Dec 31st. His decease deprives Germany of one of her prominent surgeons and the German Surgical Association of one of its most active members Professor Schede was born in 1844 at Arnsberg in Westphalia. From 1862 to 1866 he studied medicine at the Universities of Halle Heidelberg and Zürich and in 1866 he became qualified and took the degree of M D at Halle After having served in the wars of 1866 and 1871 as a volunteer surgeon he became assistant to the late Professor Volkmann the celebrated surgeon of Halle University, and remained there till 1875 being also recognised as *privat docent* In 1875 he severed his University connexions on receiving the appointment of chief surgeon to the municipal hospital of Friedrichshain in Berlin He lived in Berlin till 1880 when he was appointed chief surgeon to the Hamburg General Hospital The beautiful hospital of the city of Hamburg one of the largest in the world, situated at Eppendorf and opened in 1888 was in some particulars constructed in accordance with his recommendations Although his position at Hamburg was an excellent one owing to his being the most esteemed surgeon of that wealthy city, he nevertheless left Hamburg in order to return to a university career and in 1895 became ordinary professor of surgery at Bonn where he remained till his unexpected death Professor Schede s early publications were chiefly concerned with the treatment of diseases of the joints and especially with the use of drainage. He subsequently published memoirs on the surgery of the nerves, the spinal cord and the pleura. He also contributed the chapter on the Surgery of the Kidneys to the Handbook of Surgery edited by Professor von Bergmann Professor von Bruns, and Professor Mikulicz.

Statistics of the Medical Profession in Germany

Dr Wehmer s Medical Directory, quoted in the *Vossische Zeitung* states that there are now 28,127 medical men in Germany, as compared with 27,039 in the previous year 26 479 in 1900 26,049 in 1899, 25 178 in 1898, and 24,393 in 1897 The increase of 1088 in the number of medical men from the year 1901 to the year 1902 is an increase of 4 per cent. and is greater than in any previous year During the last five years the numerical increase of the medical profession was 3734 or 15 2 per cent., while the increase of the general population was 9 3 per cent As regards distribution throughout the various states it is found that 17,126 medical men reside in Prussia, 2790 in Bavaria, 2148 in Saxony, 1147 in Baden, 937 in Würtemberg, 814 in Alsace-Lorraine, and the remainder in the smaller states of the empire. There are 2366 medical men in Berlin, 583 in Munich, 573 in Hamburg 548 in Breslau 433 in Dresden, 431 in Leipsic, 344 in Cologne 354 in Charlottenburg, 338 in Frankfort, and 304 in Konigsberg

Prophylactic Use of Anti diphtheritic Serum

The Imperial Health Office is at present making arrangements for the holding of a collective investigation on the use of anti diphtheritic serum as a prophylactic, and with this object blank forms to be filled up have been sent to all the medical men in Germany They are, in the first place, asked to state whether this serum has ever been used by them as a prophylactic and if so they are requested to give particulars of the number of cases the age of the patients, the number of units injected in individual instances and the occurrence if any, of undesirable complications due to the injections. The replies will also specify the number (1) of those who contracted diphtheria after having received prophylactic injections and (2) of those who escaped it. Finally, the Health Office asks 'Are you persuaded by your personal experience that prophylactic injections are useful ?" The results of the collective investigation will be communicated to the International Congress on Hygiene to be held in Brussels.

Jan 5th

EGYPT

(FROM OUR OWN CORRESPONDENT)

The Medical Congress

THE Congress is now over and I have the authority of the foreign professors and other visitors for stating that it was a great success and that most of them were surprised to find how much scientific work is being done in Cairo Those of us who live here had the advantage of hearing interesting papers from Europe and America on such subjects as tuberculosis, malaria and its complications typhoid fever, dengue, and yellow fever, while we found highly interested audiences in the discussions on ankylostomiasis, bilharziosis, dysentery hepatitis, abscess of the liver, bilious typhoid fever, pellagra leprosy, insanity due to hasheesh, cholera, plague, and other diseases more peculiar to Egypt. The secretary general at the closing general meeting, in the name of the committee, drew special attention to the success of the medical section which was graced by the presence of Professor Bouchard Professor Nothnagel Professor Maragliano, Professor Chantemesse, Professor Lortet, Professor Teissier, Professor Mariani, Professor Pasquale, and many others Dr Looss contributed two interesting papers, the first proving that the skin of man and dog will allow the entrance of the larvæ of the ankylostomum worm and the second giving the life history of distoma hæmatobium and suggesting that it also may sometimes enter the skin and account for some of the mysterious ravages that are grouped together under the term 'bilharzia.' Kasr el Ainy Hospital was inspected by many interested visitors who saw there several cases of clinical interest and some special demonstrations given by Dr F M Sandwith on pellagra leprosy, and ankylostomiasis were well attended. The surgical section, though less popular than the medical, did some very good work and Mr Reginald Harrison s papers on prostatectomy and calculus were very well received. The ophthalmic section devoted most of its sittings to the consideration of granular ophthalmia and how to prevent its spread in Egypt. The pathological museum of the medical school elicited the highest praise. The specimens are prepared with great care by Dr W St. C Symmers by the formol method and are preserved in glycerine so as to show their original colours. As might be expected in Egypt there is a unique series of bilharzia lesions of the bladder, ureters, kidneys, urethra vulva, uterus, broad ligament rectum colon, liver &c, kidneys affected by ankylostoma, specimens of the red and black variety of Madura foot, dysenteric ulcerations, and specimens of elephantiasis. But what pleased our visitors most was the unique collection in the anatomical museum, arranged by Dr G Elliott Smith of specimens taken from various cemeteries in Upper Egypt, which showed human remains dating from prehistoric times at least 7000 years ago up to the present day

Fêtes and Receptions.

On Sunday the sections only met in the morning, for at 2 P M all the members of the Congress and their wives were invited by the Khedive to proceed in four of his steamers down the Nile to see the barrage which now, under English management, has for many years done for Lower Egypt what the new granite dam at Assouan will accomplish for Upper Egypt On the next evening an Arab *fête* was given by the President and secretary general of the Congress where about 800 guests had an opportunity of becoming acquainted with Egyptian singing, dancing, and conjuring tricks On the following day the Ministers received the members of the Congress after their sixth and final section meeting at the new Museum of Antiquities where M Maspero and his staff conducted eager crowds to see the famous collection of Egyptological remains. On the same evening the Khedive had invited the Congress to a ball at Abdeen Palace, but owing to the death of a princess this became impossible and therefore, to mitigate the disappointment of the visitors, he changed his invitation into an afternoon reception where he personally received all his guests. The final meeting of the Congress was, at the Khedive s command presided over by the Minister of Public Instruction, and complimentary speeches were made by all the foreign delegates after which Professor Nothnagel delivered a most interesting address in German on Prophylaxis, followed by Professor Maragliano with a paper in French on Nephritis It is needless to say that there were the usual number of private parties of hospitality including a dinner given by the School of Medicine to some of the prominent visitors a French banquet in honour of Professor Bouchard to which four English medical men were courteously invited and some popular dances given by the hotels The next Egyptian medical congress is to take place in Cairo in December 1907

Cairo Dec. 2.th 192.

Obituary.

PAUL QUICK KARKEEK, M R C S ENG , L S.A.

MR. PAUL QUICK KARKEEK died at his residence, ' Isca, Torquay on Dec .7th, in his sixtieth year On Dec. 2nd he had an attack of cerebral hæmorrhage whilst sitting in his drawing room, preparing a lecture which he was to deliver a few days later During the following three and a half weeks he was in an unconscious state, and although there were occasional slight signs of returning consciousness but little hope was ever entertained of his recovery Mr Karkeek was born in Truro and belonged to an old Cornish family He was educated at Probus Grammar School and then went to St. Bartholomew s Hospital, qualifying as M.R.C.S Eng and L.S.A. in 1865 He was then appointed house surgeon to Chester Infirmary Later he was elected assistant surgeon to the Seamen s Hospital Greenwich. On relinquishing that post he studied medicine at Heidelberg Berlin Vienna, and Paris In 1870 he returned to England married and purchased a practice at Torquay In 1878 he was elected medical officer of health of that town, which appointment he held until the time of his death Mr Karkeek was a most energetic medical officer and it was largely owing to his efforts that Torquay has such an efficient water supply He also instituted an excellent system of dairy registration in the town. Mr Karkeek was an active member of the Torquay Natural History Society and it was during his presidency in 1894 that the society commemorated its jubilee, having been founded by Mr Pengelly in 1844 by adding the Pengelly Memorial Hall to the museum buildings. The members made a handsome presentation to Mr Karkeek in appreciation of his services in connexion with the event. Mr Karkeek was highly esteemed in Torquay and much sympathy is felt there for his widow

DEATHS OF EMINENT FOREIGN MEDICAL MEN —The deaths of the following eminent foreign medical men are announced —Dr Isidor Herrnheiser the editor of the *Prager Medicinische Wochenschrift* has died from an apoplectic attack.—Dr Salomon Ehrenhaus of Berlin one of the instructors of pediatry in the vacation courses. He translated Espine and Picot s Manual of Children s Diseases" into German.—Professor Krafft-Ebing of Gratz. the well-known authority on criminal lunacy and on all forms of neuro-pathology He was 62 years of age and had been ill for a considerable period.—Dr. Michael Umnoff, formerly Professor of Comparative Anatomy in the University of Kazan at the age of 75 years.—Dr Zaayer Professor of Anatomy in the University of Amsterdam suddenly, in his sixty fifth year He had published papers on the Structure of the Osseous System, on the Condition of Bodies which have died from Arsenical Poisoning, &c.—Dr Rapin, Professor of Midwifery in the University of Lausanne, at the age of 56 years —Dr Nicoladoni, Professor of Clinical Surgery in the University of Gratz.—Dr Erlitzky a St. Petersburg alienist.—Dr A. Hénocque, vice-president of the Paris Biological Society —Dr Laroyenne, Professor of Gynæcology and Director of the Gynæcological Clinic in Lyons.

Medical News.

UNIVERSITY OF LONDON —At examinations held recently the following candidates were successful —

Foreign University Intelligence—*Berlin* Dr Pagel, *privat docent* of the History of Medicine, Dr A. Wassermann, assistant to Professor Koch in the Infectious Diseases Institute, and Dr Koblanck, *privat docent* of Gynæcology, have been promoted to extraordinary professorships, as have Dr L Katz, *privat docent* of Otology, and Dr Georg Joachimsthal, *privat docent* of Orthopædic Surgery, to titular professorships. Dr Erich Lexer, *privat-docent* of Surgery, has been promoted to an extraordinary professorship Dr Oskar de la Camp, physician to the Charité has been recognised as *privat docent* of Medicine —*Berne* Dr Gurwitsch has been recognised as *privat docent* of Anatomy, Dr Arnd and Dr Wildbolz as *privat docenten* of Surgery, Dr Hegg as *privat-docent* of Ophthalmology, and Dr A. Schönemann as *privat docent* of Otology and Laryngology —*Breslau* Dr Tietze, *privat-docent* of Surgery, has been promoted to a titular professorship, and Dr Bonhoeffer, *privat docent* of Mental Diseases, and Dr Kausch, *privat-docent* of Surgery, have been similarly promoted to titular professorhips.

The late Mr John Elliot, M R C S Eng—Mr Elliot died at his residence, Beresford, Kingsbridge, Devon, on Dec 18th aged 68 years. The deceased was the eldest son of the late Mr J Elliot, of Tresillian, and belonged to an old and honoured family which can be traced back for 300 years. Mr Elliot had been in practice in Kingsbridge for about 30 years, at first in partnership with his father and later was joined by his youngest brother Mr E A S Elliot. The deceased was formerly medical officer to the workhouse and to the local friendly societies. Mr Elliot was a widower By his death Kingsbridge has lost an old and highly esteemed townsman and one who for many years entered into all the philanthropic and charitable movements in the town.

Royal Albert Hospital, Devonport—The annual meeting of the subscribers to this institution was held on Dec. 18th under the presidency of Viscount Clifden. The medical report stated that during the past 12 months 599 in patients had been treated, against 532 in the previous year, the daily average number of occupied beds being 43 15 In the lock wards 154 women were treated. 165 patients were sent to the Pearn Convalescent Home. 1515 members are on the books of the provident branch of the hospital, compared with 1697 on the same date the previous year The financial statement showed that during the past year the income amounted to £4034 and the expenditure to £5900 leaving an unfavourable balance of £1866 It was stated that a special committee had examined the accounts very minutely and could not find any item in the expenditure which it considered ought not to have been incurred A long discussion followed the reading of the report in reference to the financial position of the hospital and it was decided to use every effort to enlist the support of the community at large. It is to be hoped that the public meetings which are to be held in Devonport and Stonehouse to arouse greater interest in the institution will result in a large and permanent increase of revenue for this excellent charity

Dr F Sidney Grimshaw, of Stillington, Yorks, has been awarded a fee of £5 by the Easingwold board of guardians, as extra remuneration for the successful performance of a surgical operation not included in the schedule

The late Mr George Evans, M R C S Eng, L S A.—The funeral of Mr Evans in Seaton parish churchyard on Dec 13th was very largely attended, amongst those present being Sir John Kennaway, M P, and Sir E de la Pole. The deceased, who was 76 years of age, was highly respected in Seaton He was formerly district medical officer of the Axminster and Honiton unions and medical officer of health of the Axminster rural district council. Mr Evan leaves seven sons, two of whom are members of the medical profession

Presentations to Medical Practitioners—Mr James Elias, M R C S Eng, L S A., who has been medical officer of health during the past six years of the borough of Neath, has recently been presented with a silver salver upon the occasion of his leaving Neath—Mr J C Heaven, M.R C S Eng, L.R C P Lond, has recently been presented with some pieces of silver plate by the members of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health upon his resigning the secretaryship of the branch, a position which he has held since its establishment seven years ago.—Mr. W Ffennell MacCarthy, M D, B Ch T C Dub., has recently been presented by the members of the Worcester ambulance class with a gold mounted umbrella

Donations and Bequests—Under the will of Mr Eli Parkinson Ackroyd of Shipley Bradford, the Bradford Royal Infirmary and Dispensary and the Bradford Children's Hospital will each receive £4000—Mr John Heneage of Richmond, has bequeathed, subject to certain bequests, his residuary estate in equal shares to the Royal Hospital at Richmond, to the Royal Free Hospital, to the Middlesex Hospital, and to the Home for Incurables at Putney—The governors of the North West London Hospital have received from the executors of the late Francis Thomas Freeman a donation of £750 out of the sum for distribution amongst charities at their discretion—Mr Thomas Cole of Sheffield by his will bequeathed £1000 to the Sheffield Royal Hospital, £1000 to the General Infirmary Sheffield, and £1000 to the Jessop Hospital for Women.—Mrs. E Dash of Bristol has bequeathed £1500 to the Bristol General Hospital, £500 to the Bristol Royal Infirmary, £500 to the Children's Hospital, Bristol, £500 to the Bristol Eye Hospital, and £500 to the Bristol Lock Hospital.

Public Health in Hong-Kong—In his report on the health and sanitary condition of Hong-Kong for the year 1901 Dr J M Atkinson, the principal civil medical officer of the colony, states that the estimated population for 1901 was 300,660 and that during the year there were 1088 births and 7082 deaths The birth rate was therefore 3 6 per 1000 and the death rate was 23 5 per 1000, for Chinese the death rate was 23 7 per 1000, while for non Chinese it was 20 5 per 1000 Plague existed in the colony during the whole of 1901, this being the fourth successive year in which it has appeared in an epidemic form As in 1900, so in 1901, the period from April to July has been the season of greatest prevalence. The numbers notified during each of these months in 1901 were as follows —April, 160, May 701, June, 551, and July, 109, making a total of 1521 notifications for these four months, with only 130 notifications for the other eight months of the year Of the 7082 total deaths 1562 were due to plague. When a death from plague has taken place in a Chinese house it is not unusual for the body to be carried out and left either in the street or in a boat in the harbour, 308 such cases occurred in 1901 and they to a great extent account for the annual recurrence of the disease, as of necessity the houses from which the bodies come are not disinfected. During the first six months of 1901 48,000 rats were destroyed. With a view to diminish the number of mosquitoes and thereby to reduce the amount of malarial fever much work has been done in removing undergrowth and draining stagnant pools of water, some benefit appears to have resulted only 541 deaths amongst the Chinese from malarial fever being returned in 1901, as compared with 887 in 1900

Notes, Short Comments, and Answers to Correspondents.

PRESCRIBING IN THE LAY PRESS

We are quite accustomed to see advice and prescriptions to patients whom the prescriber has never seen given by irregular practitioners in the columns of the *Echo* and various ladies journals but we must say that we never expected to see a fully-qualified medical man giving advice under his own name to correspondents of a newspaper And yet in a recent number of the *Burton Evening Gazette* is a column headed Health and Home by W Gordon Stables, M.D. R N Dr Stables discourses in a general fashion about convalescence and cheerfulness and the need for being careful not to catch cold in bed all of which advice is very fairly sound But at the bottom of the column come some answers to correspondents For instance E R P" is told Savours strongly of kidney trouble It would not be right to advise you in three lines what to do Consult the best man in your neighbourhood" This advice as regards its matter we have no quarrel with But further on we read Bleeding Piles (C. T R). The same ointment I frequently recommend—the compound gall, with double the quantity of powdered opium But the bowels must be kept open by confection of senna (compound) and everything of the nature of stimulants avoided" To Many (Skin Complaints Surgical Ailments and Baby Troubles) I cannot advise upon these without seeing This surely stands to reason" Exactly so then why does Dr Stables advise upon other complaints without seeing ? Can he be certain for instance that Bleeding Piles is not rectal cancer? We recommend Dr Stables to leave off prescribing in the press or anywhere else without seeing"

A PATHOLOGICAL EPITAPH.

To the Editors of THE LANCET

SIRS—Mr Ashton will find the inscription given in his letter in THE LANCET of Nov 29th 1902 p 1500 and referred to in your issue of Dec 20th p 1758 in Richard Mead's Medical Precepts and Cautions (1755) article Of the Dropsy" (p 167) It is accompanied by the following description of the case which was evidently attended by Mead himself:—

> A widow lady whose opulent estate served to render her virtues more conspicuous fell into an *ascites* in the fifty first year of her age For this she was tapped but as she soon filled up again the operation was repeated once a month for the first year and at each tapping one with another there were drawn off forty four pints of water The next year she was likewise tapped every month and the whole quantity being equally divided made twelve pints each week The third year the quantity of water began to diminish so that there was but twenty four pints for every month And in the fourth and fifth years and seven months of the sixth in which time she underwent thirty tappings, each tapping amounted only to sixteen pints. After the last time she began to grow weak and waste away and she was seized with almost a constant difficulty of breathing as we observe in a dropsy of the breast attended with frequent faintings whereas before through the whole course of the disease in the intervals of tapping she was cheerful in conversation used exercise and even diverted herself with dancing But now life began to sit heavy upon her and she died at length a very easy death Now it is very surprising that a human body in that space of time could furnish such a vast quantity of water—to wit 1920 pints and it is my opinion that this water was first collected in the ovaries In fine this good lady for the information of posterity ordered by her will that the following English inscription should be engraved on her monument [Here follows the inscription as given by Mr Ashton except that the date of death is given by Mead as March IV] And this monument is now to be seen in Bunhill Fields."

I am Sirs yours faithfully

Florence Dec. 23rd 1902. H LAING GORDON

THE CHOICE OF A PROFESSION: AN INSPIRING IDEAL

THE *Police Review and Parade Gossip* of Jan 2nd in its Children's Corner publishes a little prize essay on What I Should Like to Be written by a Welsh lad The chosen profession is that of medicine and the essay was inspired by the fact that a few years ago the competitor's sister was an inmate of an infirmary The chief reason for choosing the medical profession is the lad's desire to use his skill and to show his kindness to the poor little inmates of a children's ward" It is a sight never to be forgotten" says the writer to see a little child being parted from its mother for the first time and at a time when a mother's love and care is most needed During the eight months my little sister was away my constant prayer was May the doctors and nurses be kind to Ella. Another reason why I should like to be a doctor is so that I should be able to be good and kind to the suffering poor Oftentimes poor people are blamed because they have not called a doctor in sooner It is not for the want of sympathy and care that they don't seek advice each time that their friends are ailing It is because they are afraid of the doctor's heavy charges A single visit sometimes costs

; much as the head of a family gets in a whole week. Unfortunately it costs so much to qualify to be a doctor that a poor boy however clever he may be has very little chance to adopt that profession." he writer of the essay however hopes that by winning a valuable ntrance scholarship he may be able to enter the portals of the Temple f Æsculapius and we sincerely trust that his aspirations may be ulfilled. Such a lad ought to prove in later years an ornament to ır profession, even though, as is probable his ideal may be dimmed nd his good intentions blunted by contact with a cold and nsympathetic world.

BRITISH MEDICAL BENEVOLENT FUND

inadvertence the figures in the paragraph which appeared in our nnus Medicus relating to the above Fund referred to a month s ork only The following are the correct figures for the year 1902. a the grant department subscriptions and donations amounting to 1500 were received during the year This sum is nearly £300 less an the average for the last ten years and consequently several very istressing cases have had to be passed over A reserve of £200 was xpended. £1552 being voted to 153 recipients in grants varying from 5 to £18. In the annuity department the income available from ıvestments was £2,00 and 115 annuitants received £2290 Many of ıe cases still standing over are in great need of immediate help and ıoney is urgently required to enable the charity to meet the demands made upon it The committee appeals very earnestly for ıcreased support and especially asks the friends of the Fund to iterest others in its work. Subscriptions and donations will be ratefully received by the treasurer Dr Samuel West 15 Wimpole-tree W., or by Mr W E. Sargant St. Bartholomew's Hospital, .C (honorary secretary for cases)

THE EVANGELIST BROTHERHOOD

To the Editors of THE LANCET

IRS,—In replying to the somewhat uncharitable clipping from E LANCET in which your correspondent refers to me as the anadian quack," I take up the cudgels not for myself but for the ıusands of broad minded investigators scattered throughout this ıtinent who use the same means to promote the cure of disease as I whenever practicable. As an Englishman I claim the right of umed innocence until proven guilty this is my legal privilege and ral right, even in a Court of Law Your correspondent denies me n this

The fact remains that Mr Colvile has under God's blessing been tored to health by a simple system of treatment which sets up especial claim other than that of being in accordance with a Divine promise voiced in St Matt. xviii. xix. *This system has* thing to do with Christian Science so-called, as is often supposed by me, neither is it mystical, magical nor *specially miraculous. It is* ıinently scientific, being based upon certain laws in physics and ing the demonstration of certain *principles* in metaphysics both of ıich are phases of truth. Personally I *heal* no one by this method y aim is to *teach* certain *principles*, which if followed faithfully ʼng into being perfected results as a consequence of compliance th laws which constitute the agreement referred to in . Matt., xviii.-xix. Perhaps if your journal lent its pages to oad minded inquiry *instead* of hard words against those o like myself have given up everything they possess in e cause of truth it might assist those suffering millions wards gaining that freedom which only the truth appropriated similated and manifested can give As to my charge of £3 10s any people write to me and my time has a financial value. It has en my *privilege to see* drunkards reclaimed, so-called incurables" stored to robust health, the mentally afflicted relieved and numbers people of every age, disease and shade of opinion assisted by this ıem of healing which is in compliance with Nature's laws.

In conclusion, your journal is welcome to its opinions but owes a ıty to the public—viz. to honestly investigate that which once derstood so directly pertains and contributes to the public good. onclude by quoting the much worn passage There are more things heaven and earth Horatio [and on this continent] than are dreamt in your philosophy"

Yours in the cause of truth,

Winnipeg Man., Dec. 2nd 1902.

H. AYLMER HARDING

,* No correspondent has denied Professor" Aylmer Harding anything We have said what we think and his communication does not lead us to alter our opinion of his methods When a man, not being a medical man, claims in the same breath to be of those who have given up everything they possess in the cause of truth" and to be entitled to high fees from patients because "my time has a financial value" he is lucky if he is called nothing worse than a quack.—ED L.

ADVERTISEMENT

ʼE have received copies of a circular of the North Croydon Benefit Slate Club which is stated by a correspondent to have been distributed broadcast in the neighbourhood The circular which sets out the various advantages to be obtained by males and females between the ages of 16 and 53 years through joining the association states among these advantages that medical attendance and medicine will be obtained from Dr Addison We are informed that this circular has been delivered in one road from house to house, while two of the copies which have been sent to us were picked up lying in the street Dr Addison is advised to take immediate steps to stop the publication of a handbill bearing his name and using his professional position as a bait to attract members to the North Croydon Benefit Slate Club. These circulars have been left upon the patients of other medical men and the General Medical Council has expressed a very strong view as to the unseemliness of medical men serving any association or society which touts for members. We shall be glad to learn that Dr Addison has not only instructed the secretary immediately to suppress the offensive handbill but that its dissemination has been entirely without his knowledge

AN ATTACHMENT FOR SERVIETTE RINGS AND OTHER ARTICLES USED AT TABLE.

MR. H. B BUTTERWORTH of Newcastle, Staffordshire has sent us photographs of what appears to be a useful appliance. At hotels, hydropathic establishments and other places where considerable numbers sit at table together it sometimes happens that a guest who has sent a plate or cup to be replenished receives back not the one he had been using but a plate or cup belonging to someone else. To avoid this unpleasantness Mr Butterworth has devised and is about to obtain protection for a clip which may be fixed on the edge of the plate or cup and bears a number corresponding to that of the guest's place at table, or any other number serving for identification. The clip may also be attached to serviette rings and will answer the purpose of fixing a serviette to the coat or waistcoat

SPITTING AND THE SPREAD OF TUBERCULOSIS

THE Public Health Department of the Urban District Council of Acton has issued a notice requesting the public not to expectorate on the ground but into proper receptacles for it says Spitting is the main source of the spread of consumption" This notice has vexed the soul of a gentleman who lives at Acton and who incloses us the following announcement which we suppose is drawn up by himself —

CONSUMPTION,

PNEUMONIA THROAT CATARRH, &c

It is certain all expectorations should be religiously re-swallowed. We have found a simple sip of cold milk with the phlegm in the mouth, forms a perfect throat healer and this matter together being returned to the system arrests at once the gradual decay so distressing to witness, if spit away No Cod Liver Oil or Emulsion needed—no Lozenges to ease the throat. At first sight it may appear unclean, but it is our own impurity and dust we are and to dust we must return If the faculty really have decided that this present mode of spitting is a cause of contagion to tens of thousands, then for the welfare of the general public alone they should at once insist on this being done.

The swallowing of all expectoration would certainly prevent the dissemination of tuberculous matter by sputum, but there is such a thing as auto-infection. Other diseases such as typhoid fever are spread by excreta and we do not think that our correspondent would be prepared to carry out his advice to its logical end and consume the other waste products of his economy

INDUCEMENTS TO DRUNKENNESS

AN esteemed correspondent has sent us a copy of a circular issued by an institution called the Wine Club Limited of 46 Dover-street, a club which offers to its associates (who can become associates without election upon payment of one guinea per annum in advance) the advantages of buying wine cheap. It is not however with the constitution or purpose of the Wine Club that we have any fault to find but with the advertisement which is circulated of a cocktail, which we do not name, prepared and bottled by American merchants who shall also remain anonymous.

THE —— COCKTAILS.

FOR TIRED WOMEN

As a tonic, —— Cocktails should be in every home. They will put new life in one after a day's hard shopping Endless worry of household duties can be done away with, if the needed tonic is at hand. As a ladies drink, The —— Cocktails" has no equal.

FOR TIRED MEN

After a busy day see that you have at home a bottle of —— Cocktails. As an appetizer and general tonic for the business man they have no equal.

We have no hesitation in calling such advertisements wicked. They suggest the ingestion of stimulant in the most dangerous way on the most dangerous occasions

THE ANTI VACCINATIONIST

IN applying to Mr Mead at the North Western Police-court on Dec. 12th for an exemption certificate for his child under the Vaccination Act a working man propounded the following conundrum to the learned magistrate — If vaccination will keep small pox away why can't they vaccinate us to make us live for ever?" The application of this conscientious objector" was refused. In another case heard on the same day at the Thames Police-court a woman pleaded guilty to making a false statement to the registrar when registering the birth of her child. It was stated in evidence that the child was born at 164 St. George's-street where the parents still lived, but that the registrar had been informed that the birth had taken place at 65 St George's-street and that owing to the fact that a number of similar false statements had been made by persons desiring to avoid having their children vaccinated the Registrar General had ordered a prosecution in this instance The defendant frankly told the magistrate when questioned by him that her object in making the false statement was that she might if possible avoid having her child vaccinated The child had since been vaccinated and Mr Dickinson only inflicted a fine of 40*s* and 2*s* costs informing the defendant however that for the offence that she had committed a sentence of seven years penal servitude might be passed The accurate registration of births is of obvious importance not only with a view to vaccination in due course but also in order that the lives of infants may so far as is possible be protected

PRACTICE IN CALIFORNIA.

To the Editors of THE LANCET

SIRS —In answer to the inquiries of J D" in THE LANCET of Dec 20th 1902 p 1738 I beg to inform him that I practised in California for two years To enable any properly qualified British medical man to practise there he will have to send his diplomas up to the secretary of the University of Southern California at San Francisco and also two certificates from medical practitioners here stating that he is of good honourable repute and of good character in all ways at the same time applying for a licence to practise there which he will have to register wherever he commences practice

I am Sirs yours faithfully

Macclesfield Dec 22nd 1902. J WESTMORLAND

To the Editors of THE LANCET

SIRS —In reply to your correspondent J D who in THE LANCET of Dec. 20th 1902, p 1738 asks about practice in California—1 A medical man wishing to practise in the State of California must have a diploma recognised by the Board of Medical Examiners and this diploma must in nowise fall below the standard prescribed by the Association of American Colleges for that year 2. The applicant must produce this diploma along with an affidavit stating that he is the lawful possessor of the said diploma and that it was obtained in the regular course of instruction and examination 3 The applicant must furnish satisfactory testimonials of good moral character 4 In addition to the above he will be personally examined in the following subjects: anatomy physiology bacteriology pathology chemistry and toxicology surgery obstetrics materia medica and therapeutics theory and practice of medicine A general average of 75 per cent must be obtained The examination will be in whole or in part, in writing The fee is $20 which should accompany the application The secretary of the board is George G Gere M D I can certify from inquiries conducted through two channels that these formalities are incumbent on anyone intending to practise in the State of California and I have made a *précis* for your correspondent of the significant parts of the orders and regulations

I am Sirs yours faithfully

Dec 20th 1902 E

MOTOR CARS FOR MEDICAL MEN

To the Editors of THE LANCET

SIRS —For the information of your readers I wish to state that I have had a locomobile steam car for almost two years I have worked it in my ordinary rounds alternately with a horse in all kinds of weather I have had no unexpected stoppages on the road I have looked over my books and find that the cost of running for the whole period has been £56 7*s* 11*d* of which £26 was for petrol and the remainder was for repairs renewals and improvements The car looks as well as when I bought it and runs much better owing to the improvements I have had added I find it most useful for long country rounds it saves so much time

I am Sirs yours faithfully

Loughborough Dec. 10th, 1902. THOMAS CORCORAN

MEDICAL MISSIONARY WORK.

To the Editors of THE LANCET

SIRS —I should be glad if any of your correspondents could furnish me with particulars of medical missionary work abroad—as to the societies which send out medical missionaries and the requirements necessary to meet the demands of such societies

I am Sirs yours faithfully

Jan 6th 1903 E B

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

To the Editors of THE LANCET

SIRS —The annual report of the Royal College of Surgeons of Edinburgh affords much useful information and shows that the value of the Fellowship diploma—to judge by the number of admissions—is rapidly rising in the estimation of the profession and that this increase is not due to any greater leniency on the part of the examiners for 1902 as 36 per cent of the candidates as against 21 per cent. were rejected I think that the explanation lies in the fact that the Edinburgh College has for some years ceased the one-time common custom of admitting Fellows without any professional examination simply by ballot; during the past 10 years this privilege has only been granted six times I find that out of the 840 Fellows whose names appear on the roll Scotland can only claim 150 and of these 96 reside within the Edinburgh postal radius and of these 33 are examiners for the Fellowship while in England and Wales there are 420 Fellows Of these many are men holding high positions in our profession and I submit it is now time the non resident Fellows should take a more active interest in the affairs of the College Why should we not form an association of Fellows practising in England? Why should the examinership be confined to Edinburgh men? Would not the inclusion of new men still further advance the value of the diploma? Could not an organised attempt be made to found lectures as in the English College? Now that the College has extended its borders should not the majority take greater interest in its working and be better represented on its committees? I throw out the suggestion and remain

Yours faithfully

Jan 3rd 1903 F R C S EDIN

PLAGUE IN SAN FRANCISCO

THE seventeenth annual meeting of the State and Provincial Boards of Health of North America was held at New Haven Connecticut, on Oct. 28th and 29th 1902 In its report of the proceedings the December number of the *Yale Medical Journal* states that the following resolution was adopted expressing the opinion of the conference as to the conduct of the health authorities of San Francisco —

Whereas Bubonic plague has been present in California since March 1900 complete information as to the extent of the disease being withheld by the local authorities no effective measures of restriction having been put into operation and

Whereas Twenty five of these cases have occurred in the months of July August September and October 1902, no information as to their origin or exact location having been furnished, no effective steps having been taken to restrict the spread of the disease the City Board of Health of San Francisco being helpless, and the mala fides of the State Board of Health of California having been fully established by the foregoing history supported by documentary evidence in the possession of this conference therefore, be it

Resolved, That the Conference of State and Provincial Boards of Health of North America views with abhorrence the irretrievable disgrace of the present State Board of Health of California, and pronounces the plague situation in California a matter of grave national concern

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* ' TO THE EDITORS and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed ' To the Sub Editor '.

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed ' To the Manager '*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol II of 1902, which was completed with the issue of Dec 27th, and the Title page to the Volume, were given in THE LANCET of Jan 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18*s*, carriage extra.

Cases for binding the half-year's numbers are also ready Cloth, gilt lettered, price 2*s*, by post 2*s*. 3*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months ...	0 17 4
Three Months	0 8 2	Three Months ...	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

&c. These cases must be treated on the lines already indicated.

6. The last class of difficult and bad subjects comprises those who give trouble to the anæsthetist without any discoverable cause. As our clinical knowledge increases these cases become more and more exceptional and it is to be hoped that as time goes on the class will cease to exist altogether I have notes of a few of these interesting and exceptional cases and they certainly seem to my mind to warrant the retention of the term "idiosyncrasy" As an example I may mention that I have known certain peculiar and highly inconvenient nervous phenomena occurring in connexion with the use of nitrous oxide to be displayed by more than one member of a family Unfortunately the opportunities one has of investigating these peculiar cases are very limited, whilst the history obtainable from patients or their friends is often unreliable. I regret to say that the data at my disposal are not sufficient to enable me to give you any useful information concerning patients of this class.

In concluding these imperfect lectures in which I have attempted to direct your attention to an aspect of the subject of anæsthesia which has not perhaps attracted sufficient notice, let me say that I hope I have not given you the impression that every case with which you will have to deal will be a difficult one. Difficult and bad subjects are comparatively rare, but when considered in the aggregate they admit of some such classification as that which suggested itself to me. I can only add that if I have helped you to understand any exceptional cases that may already have come under your notice, or if I have succeeded in fixing within your memories mental pictures of those subjects who, when you leave your hospital and go into practice, are most likely to give you trouble, I shall feel that the time that has been so pleasantly spent in preparing and delivering these lectures has not been altogether wasted.

A Clinical Lecture

ON

THE INTRACRANIAL COMPLICATIONS OF SEPTIC EAR DISEASE

Delivered at the Medical Graduates College and Polyclinic on June 15th 1902,

BY FREDERIC EVE, F R C S ENG,

SURGEON TO THE LONDON HOSPITAL CONSULTING SURGEON TO THE EVELINA HOSPITAL AND MEMBER OF THE COURT OF EXAMINERS ROYAL COLLEGE OF SURGEONS OF ENGLAND

GENTLEMEN,—I propose to consider with you to-day the intracranial complications following suppurative or septic inflammations of the middle and internal ear and mastoid antrum. It is unnecessary to speak of the important relations which these structures have with the meninges, the lateral sinus, and the brain itself This being a clinical lecture I shall make no apology for illustrating my remarks as far as possible by reference to cases which have come under my care.

Pachymeningitis externa —The first and least important complication to mention is pachymeningitis externa—a thickening of with formation of villous granulations on, the external surface of the dura mater. It is most common over the sigmoid bend of the lateral sinus and is frequently associated with the formation of pus between the bone and dura mater I observed this change over the anterior surface of the temporal bone in a recent case of temporo-sphenoidal abscess It may be regarded as a danger signal. A similar change may exist on the inner surface of the dura mater and thus septic organisms may pass to the lymphatics of the pia mater and brain leading to meningitis or cerebral abscess.

Extradural abscess —The formation of pus between the skull and dura mater is much commoner over the sigmoid sinus but may exist over the roof of the tympanum or antrum or over the internal auditory meatus. When in suppurative mastoiditis the antrum is dilated it frequently happens that the thin partition between this cavity and the lateral sinus is absorbed, the sinus being then bathed in pus I have met with this condition many times and have been surprised at the slight character of the symptoms, probably because the pus is not shut up under considerable pressure. Last year I performed mastoidectomy on a lady the day after she had travelled from Gloucestershire. The mastoid antrum was greatly enlarged and filled with pus, and the lateral sinus exposed for from one to one and a quarter inches, yet her only symptoms were severe pain over the mastoid region and side of the head, moderate pyrexia, and somewhat profuse otorrhœa. She made a rapid recovery without further complication, and this is the usual sequence

The symptoms associated with suppuration around the sigmoid sinus when its bony walls are intact are somewhat more severe, yet not so marked as might be anticipated, seeing that pus is confined under pressure in immediate contact with one of the largest venous channels in the body Of five cases the notes of which I have before me in not one was a *rigor* observed. The usual symptoms are those of acute mastoiditis—local pain, hemicrania referred to the posterior half of the side of the cranium and sometimes located just below the parietal eminence, perhaps tenderness on percussion or local œdema behind the auricle, otorrhœa or history of recent otorrhœa, and finally moderate pyrexia. In addition there are sometimes severe constitutional disturbance with vomiting giddiness, and mental confusion. In one patient, a Post Office sorter, aged 23 years, who was under observations 12 days before the operation, the symptoms were of such a character as to suggest cerebral abscess. He had otorrhœa on the left side when a boy This stopped and recommenced a fortnight before he came under observation A week later he complained of giddiness and confusion in recognising addresses on letters, with occasional unsteadiness of gait Finally, vomiting came on with the usual symptoms of acute mastoiditis. On admission haziness of the discs was observed, but no actual neuritis The temperature was subnormal to 99° F and the pulse was from 64 to 67 He recovered completely after mastoidectomy and evacuation of a considerable amount of pus around the sinus

The presence of pus around the sigmoid sinus fortunately very frequently reveals itself after the mastoid antrum is exposed by the exudation of pus from a small channel opening on the posterior wall of the mastoid antrum It is probably a small venous channel and if followed up with the gouge or burr leads directly to the purulent collection. I have repeatedly been led to discover an extradural abscess by its means. An extradural collection of pus above the anterior surface of the petrous bone may reveal its presence on examination with the otoscope by the dripping of pus through an opening in the roof of the attic into the tympanum. This symptom may also be present in temporo-sphenoidal abscess.

Treatment.—In all these cases mastoidectomy is required. A collection of pus around the sigmoid sinus can be readily evacuated by enlarging the opening in the temporal bone backwards in the direction of the base line. If it be situated above the tegumen it can be opened by enlarging the osseous cavity upwards in the direction of the superior wall of the bony meatus.

Thrombosis of the lateral sinus.—The deposition of clot in the sigmoid sinus most frequently follows the formation of pus around it or the growth of septic granulations from the mastoid cells through the bony partition which separates them from the sinus Or it may result from the extension of a septic thrombus along small veins which pass from the tympanum and mastoid antrum directly into the lateral sinus Lastly it may rarely result from extension of a clot primarily originating in the superior petrosal sinus. The symptoms produced are general and local. The general symptoms are those resulting from breaking down and dissemination of septic clot and may be summed up as those of pyæmia superadded to those of acute mastoiditis—rigors pyrexia with marked fluctuations of temperature, vomiting, with in some instances symptoms of cerebral disturbance. In the majority of cases the prominent symptoms are referable to the occurrence of septic embolism in the lungs In others the septic intoxication manifests itself in profuse diarrhœa, meteorism, abdominal pain, extreme exhaustion and a general condition which has been mistaken for enteric fever Finally, the thrombosis may be complicated with meningitis the symptoms of which mask those of the sinus lesion.

rapidly takes place. In extreme cases of alcoholic indulgence nitrous oxide may be practically useless as an anæsthetic, at all events from the surgeon's point of view I have, in fact, in one or two instances been obliged to resort to ether in order to obtain sufficient anæsthesia for a simple dental operation. The worst cases are those in which the patient, apart from the question of alcoholism, is himself a difficult subject.

I have been very interested in the influence which the excessive use of tobacco undoubtedly has in disturbing and modifying the usual phenomena of anæsthesia. Great smokers may be quite as difficult to anæsthetise as great drinkers Repeated swallowing, hesitating and suspended breathing, the excessive secretion of mucus, inconvenient muscular rigidity, especially about the jaws and neck, obstructive stertor, dilated pupils, and exaggerated reflexes are common incidents in the anæsthetisation of these patients So much anæsthetic may be needed to produce a proper degree of anæsthesia in an excessive smoker that the toleration may be erroneously attributed to alcohol. In two cases of which I have notes—one that of a dark, muscular man 45 years of age who had smoked 30 cigars during the three days preceding the operation, and the other that of a man of about the same age who "always had a pipe in his mouth except at meal times"—I was obliged to push the anæsthetic to an almost dangerous degree before I could obtain anything like a good anæsthesia In both cases ether was taken so badly that I had to change to chloroform. In another case, that of an officer in the army who smoked to excess, I had somewhat similar difficulties coupled with asphyxial symptoms from jaw spasm. But as this patient had given so much trouble to another anæsthetist that he (the anæsthetist) had had to deprive him of nine teeth before he could get him to breathe, my task was a comparatively easy one One of the most difficult patients I have ever had to anæsthetise was a great smoker He was a middle aged man, a waterman, and an in patient of this hospital He had barely audible heart sounds and a slow pulse. He smoked "plug" tobacco Ether was very badly borne and chloroform, to which I changed, produced no better result. Intense jaw spasm, mucous rattling with expiration, cyanosis, and general rigidity combined to make the administration very difficult, and I am bound to confess that I was unable by any device to obtain an anæsthesia which satisfied me. Fortunately such cases are exceedingly rare The intensity of the jaw spasm in these smokers is interesting It seems to suggest that by the suction, puffing and other movements essential to the smoking of a pipe, cigar or cigarette some muscular hypertrophy takes place, the result being that during the stage of general muscular rigidity, which is usually marked in these subjects, considerable spasm of the muscles about the jaws and floor of the mouth occurs

5 From a careful study of the preceding classes of difficult and bad subjects it will, I think, be clear to you that if in any given patient we find associated the characteristics of one or more of these four classes our difficulties will be proportionately greater With the object of making my meaning clear I have up to this point endeavoured to present to you pictures of patients who are difficult or bad subjects by reason of their having a single distinguishing feature or peculiarity But in practice these pure types are not common Thus, some of our greatest athletes have nasal obstruction, and a combination of a highly developed muscular system, a blocked nasal air way, and good teeth may readily give trouble unless precautions are taken. Young officers in the army, of athletic build, may by the excessive use of tobacco prove to be very unsatisfactory subjects even for nitrous oxide. The combination of muscular development, nasal obstruction, and excessive smoking will still further embarrass the inexperienced anæsthetist. When we come to add what I may term the alcoholic element the combination becomes even more unwelcome. But in all cases such as I have just mentioned you will find that by providing for, and maintaining a free air way and by steadily administering large doses of ether till you attain the desired degree of anæsthesia you will overcome your difficulties. Powerfully built young men who have drunk very freely may require so much anæsthetic to abolish reflex movement that the spasmodic tongue retraction—which in certain subjects of this type takes place in deep anæsthesia—actually occludes the air way and the anæsthetist may find himself in a dilemma. In order to maintain a free air-way the tongue must be drawn forward, whilst chloroform, the only possible anæsthetic, is freely given. When the type of your patient changes, so to speak, from the young, thin, and muscular to the young and fat, or young, fat, and muscular, and when such complications as nasal obstruction, good teeth, a receding lower jaw, alcoholic indulgence, and excessive smoking are present, considerable difficulties will be liable to arise. It is in such cases as these that the use of the nitrous oxide ether sequence may be attended by trouble, more especially if no mouth prop has been inserted before commencing the administration and if the bore of the inhaler be narrow The best plan, as a rule, is to employ the C E -ether sequence or if the ether be badly borne the C E. ether chloroform sequence. If the C E mixture or chloroform be used throughout it is difficult or impossible to avoid struggling Should the anæsthetist especially wish to administer nitrous oxide and ether a mouth prop must be inserted and a wide bore inhaler used, in which circumstances a fairly good result may generally be relied upon Somewhat allied to patients of this type are middle-aged or elderly men who, from having eaten and drunk too freely and from having lived sedentary lives, have become corpulent and breathless on exertion Such patients are not, so far as my experience goes, quite so difficult to manage as are younger subjects. Speaking generally, the best line of treatment to be adopted is gradually to administer the C E mixture, to be most careful to provide for and to maintain an oral air-way throughout, repeatedly to withdraw the anæsthetic during the stage of rigidity and to substitute chloroform for the mixture should indications of ether irritation present themselves The most critical juncture with such subjects occurs during the stage of rigidity and it may be necessary at this stage to adopt one or other of the numerous little devices which are available for preventing an undesirable suspension of breathing in order to avert any risk of syncope. Finally, we come to the worst subjects of all—those who not only present difficulties by reason of their belonging, when in their usual state of health, to difficult types, but who present, in addition, difficulties dependent upon some recently acquired and grave constitutional disorder Thus when a stout breathless old man who has smoked and drunk to excess and has for years suffered from nasal polypi is seized with symptoms of acute intestinal obstruction, no worse subject can be imagined. The issue of such a case depends largely on the skill of the anæsthetist. One of the most important points in these anxious cases is the posture of the patient. The nearer he can be brought into the lateral position the better, for in this position the ejection of the contents of the stomach will be comparatively free from risk. It is often possible by placing pillows under one shoulder to obtain the advantage of the lateral posture without interfering with the position of the pelvis. The mouth should be kept open by a Mason's gag, mucous or other fluids within the fauces should be repeatedly sponged away, and a moderate anæsthesia obtained. Generally speaking, an ether and chloroform mixture, suitable to the particular case should be employed As another instance of an exceedingly bad subject I may mention the alcoholic man of corpulent or burly build, who, having been seized with pleuro pneumonia, requires an anæsthetic for an operation for empyema. In certain desperate cases of this class the administration of even a small quantity of chloroform may prove fatal, the patient dying, not from the toxic effect of the drug but from cardiac syncope dependent upon the slight additional embarrassment of breathing incidental to the excitement stage. Although apparently opposed to all recognised principles I hold that in such cases the safety of the patient is best consulted by employing the A.C E. or C E mixture for the first half minute, then substituting for it ether on a semi open inhaler, and subsequently keeping up merely a light anæsthesia. One of the worst subjects I ever had to anæsthetise was a youth 17 years of age who had been an imbecile from birth, and who had, prior to the operation at which I assisted, suffered from diphtheritic paralysis and mitral disease. He now had pyopneumothorax and was sitting up, with a very feeble pulse and in a state of much dyspnœa. I adopted the treatment to which I have just referred and free pleural drainage was successfully established As instances of similarly desperate cases I may mention patients who, being originally bad subjects, have become worse subjects by reason of such conditions as angina Ludovici, septic pharyngitis, tonsillitis, laryngitis,

the posterior surface of the pons at the situation of the nuclei of origin of these nerves. There was also a cheesy nodule in the middle lobe of the cerebellum. It is probable that the meningitis was recent and of septic origin, the tuberculous formation being a coincidence In another case in which my opinion was asked a child, suffering evidently with meningitis, had symptoms suggestive of temporo-sphenoidal abscess—i e., otorrhœa on one side and paresis of the face and upper extremity on the opposite side. A diagnosis of tuberculous meningitis was made and this proved to be correct, the paresis being due to a mass of tuberculous granulations in the lower part of the Sylvian fissure

Cerebral abscess—This occurs in two situations in ear disease the temporo-sphenoidal lobe and the cerebellum Certain general symptoms are common to abscesses in both situations vomiting having no relation to food, intense pain sometimes of a paroxysmal character, foul breath, rigors varying from slight chill to violent shivering, giddiness, and lethargy The latter is one of the most important symptoms The patient lies in a somnolent condition approaching that of coma, but can be roused, answers questions rationally, although the answer is delayed. There may be want of sustained attention The temperature is usually characteristic. From the septic type which accompanies mastoid inflammation it suddenly falls to normal, and during the late hours of the night and early morning is often slightly subnormal. The pulse and respirations are generally slow especially in large abscesses but in all the examples (with two exceptions) of cerebral abscess that I have met with the pulse has been rapid, about 120, although the temperature has usually conformed to the characteristic type. Optic neuritis is present in the majority of cases. The following case illustrates some of the special features of abscess of the temporo-sphenoidal lobe.

A woman, aged 24 years, was first seen by me at the London Hospital at midnight on Feb 20th of last year Her history was that at Christmas the ossicles were removed from the right ear and two weeks before admission a polypus was destroyed by a surgeon at her own home After the latter operation the temperature rose and she was supposed to have erysipelas. There were profuse discharge from the right ear and at times delirium, but neither vomiting nor rigors Her condition on admission was as follows. There were lethargy and inattention to questions which appeared to be mainly due to the deafness, extreme œdematous swelling on the *right* side of the head, face, and neck, purulent discharge from the *right* ear and slight right facial paresis. The pupils were equal and mobile, there was no optic neuritis. The knee-jerks were brisker on the left than on the right side. No paralysis of the limbs was observed. The pulse was 72 and the temperature was 101 6° F Operation—The mastoid antrum was opened in the usual way and a large accumulation of pus was let out from beneath the temporal aponeurosis and pericranium. There was no thrombosis of the lateral sinus, but pachymeningitis externa was observed on the dura mater covering the anterior surface of the petrous bone The next day she was quite bright and talked readily The improvement continued until the morning of the 23rd when the pulse fell from 96 to 56 and the temperature suddenly to 97 4° She had become extremely drowsy and I observed slight paresis on the left side of the face of the cortical type, the orbicularis oculi being unaffected. There was also marked weakness of the left upper extremity, the grasp of the left hand being five, while that of the right was 75 A temporo-sphenoidal abscess was diagnosed A second operation was performed. The incision previously made was prolonged vertically upwards above the external meatus and a considerable portion of the squamous bone was removed with Hoffmann's forceps in the same direction. The dura mater which bulged through the opening was incised, and a large abscess was at once found by inserting a trocar It was very freely opened irrigated to remove sloughs of brain tissue and a drainage tube was inserted I suspected that there might be another abscess cavity in the neighbourhood and therefore inserted my finger into that which was found and passed a trocar into the brain substance in the neighbourhood but did not open the second cavity The patient improved after the operation but on the 26th (three days later) symptoms of compression returned, the pulse remained slow and the temperature subnormal. Operation was performed a third time The opening in the skull was again prolonged upwards for another two inches so that its upper limit was about two and a half inches above the upper margin of the bony meatus. A second still larger abscess was opened. The cavity extended inwards for at least two inches and was about two and a half inches in diameter On the following day the mental torpor was much diminished the grasp of the left hand was much stronger the pulse was from 110 to 120, and the temperature was 99·2° On March 10th the patient had steadily improved, the grasp of the left hand was 30 and the right was 70, left facial paresis was still present but lessening The discharge from the abscess soon ceased and a hernia cerebri developed which sloughed for a time but ultimately became covered with healthy granulations The discs remained quite clear Her subsequent progress was only interrupted by the formation of a small collection of pus under the temporal fascia and she is now in good health

In another case of right temporo-sphenoidal abscess in a man, aged 21 years, the symptoms were precisely similar—i.e., there were paralysis of the left face and paresis of the left hand and arm also twitching of the right side of the face. Immediately before operation the pulse was 64 and the temperature ranged from 100° to 101° F There was no optic neuritis, although the right disc was blurred The subsequent progress of the case showed that septic inflammation had already extended to the lateral ventricle The temperature rose to 103° he became noisy and delirious with retraction of the head, and finally died three days after the operation. The right lateral ventricle contained purulent fluid and communicated with an abscess cavity in the posterior part of the temporo-sphenoidal lobe Extending from the abscess cavity downwards was a channel which opened on the under surface of the temporo-sphenoidal lobe above the tegmen.

Paresis of the face and upper extremity on the opposite side, so often present in temporo-sphenoidal suppuration, is due to the abscess extending upwards or upwards and inwards and pressing either upon the cortex of the ascending central convolution or upon the nerve fibres as they pass from it, so that the face will be first affected, then the arm while the leg escapes. Among other symptoms often present and not existing in the cases above related may be mentioned dilatation with immobility of the pupil on the same side and paralysis of the third nerve on the same side. Deafness on the opposite side from disturbance of the auditory centre has also been observed, and if the abscess be situated on the left side aphasia may exist from pressure upon the posterior end of the third frontal convolution The patient as a rule lies with the limbs flexed and the affected side undermost, a position just the reverse of that observed in cerebellar abscess

Cerebellar abscess—The following case illustrates nearly all the typical features of this lesion. In August, 1900, I saw in consultation with my colleague Mr Mark Hovell, an employé aged 43 years, in the telegraph service abroad who had been sent home on account of acute ear trouble. He had noticed discharge from the *left* ear at intervals since the age of 14 years About June 24th he began to suffer from cephalalgia and on August 7th he left his employment for London where he arrived in the following condition There was extreme lethargy with irritability when roused, the breath was offensive, he lay on his right side and immediately turned over to that side when placed on his back The pupils were of moderate size, sluggish, and there was distinct optic neuritis of both discs but most marked on the side opposite to the lesion. The grasp of the left hand (that on the same side as the lesion) was distinctly weakened but no alteration of the face or leg was observed and the knee-jerks were natural and the same on both sides The temperature was 96 4° F but the pulse was 120 Left cerebellar abscess was at once diagnosed. Operation was as follows The evacuation of the abscess being the most important point the ear itself was left for a future procedure The cerebellum and lateral sinus were exposed by applying a trephine one and a quarter inches behind the posterior margin of the meatus in the direction of the base line. There was a small collection of pus around the sigmoid sinus, the dura mater over the cerebellum was much bulged extremely tense, and without pulsation. On inserting a trocar in a direction forwards and inwards an abscess was found containing four or five ounces of pus The lateral sinus for some distance was thrombosed and its wall at one point was destroyed. The

Local signs —The only distinctive local signs are "cord like" induration along the course of the internal jugular vein due to extension downwards of the clot and peri phlebitis, and tenderness at the apex of the posterior triangle resulting from thrombosis or phlebitis of the posterior cervical veins which communicate with the lateral sinus Œdema of the integument over the mastoid process is also said to be often present, but it probably is mainly due to the co-existing ostitis It should be borne in mind that the discharge is prone to cease at the onset of thrombosis and if the case has only just come under observation, the surgeon may hold his hand in doubt if the case is really one of ear disease. Cases of otorrhœa and mastoiditis with intracranial complications are apt to be associated with quite insignificant local symptoms of inflammation, because many are instances of long standing otorrhœa which has resulted in sclerosis of the mastoid bone. Consequently the antrum is deeply placed, covered often by a layer of sclerosed bone from three quarters to one inch thick, it may be this circumstance which determines the extension of the septic process inwards instead of outwards It is evident that the *characteristic* symptoms of sinus thrombosis are only present in the majority of instances when the disease has reached a stage at which treatment is almost hopeless. Our aim should be to recognise the disease before the clot has commenced to disintegrate. In four cases which I have before me this was accomplished In all of them pus existed around the sigmoid sinus and was the cause of the thrombosis. Hence the symptoms may mainly be referred to it. In not one of the four cases was there a rigor In three vomiting was a prominent symptom In two there was drowsiness, in two there was incontinence of urine, and in two cases there was tenderness or pain along the course of the internal jugular vein In any case, therefore, in which pyrexia, with vomiting, drowsiness, or incontinence exists the lateral sinus should be exposed This can be done in the manner mentioned in describing the treatment of extradural abscess around the sinus A clot can be recognised readily by palpation Where doubt exists as to the presence of clot the sinus should not merely be punctured with a trocar but should be opened Free bleeding follows but is effectually stopped by a compress of gauze When a clot is clearly present the internal jugular vein should be ligatured first and subsequently the sinus should be incised and the clot removed. If it be breaking down it may be necessary to flush the jugular vein by injecting from the skull into the wound in the neck. The patients in all of the four cases above mentioned recovered excepting one who died from meningitis

Meningitis —Septic lepto meningitis is so common that I need not trouble you by detailing the symptoms It may, however, be of interest to quote cases of the rarer forms of meningitis sometimes associated with ear disease

Serous meningitis —The following is an example of serous meningitis with internal hydrocephalus The patient, a girl, aged two years, was admitted to the medical wards of the London Hospital on July 19th, 1895, with retraction of the head which had existed for two weeks, vomiting and sore-throat. The pupils and fundi were natural On August 1st an offensive discharge from the nose was observed. On the 5th I was asked to examine the eyes and found the left disc normal and the right somewhat blurred The child appeared better and the retraction of the head had disappeared On the 10th discharge from the right ear was first noticed, with slight tenderness over the mastoid. The head was more retracted and the temperature was normal On the 16th she was transferred to the surgical side, when the right mastoid was opened and pus was found The membranes and brain were then explored with a negative result. The child died on the 20th and at the necropsy the lateral ventricles were found to be enormously distended with clear fluid The choroid plexuses were thickened and flocculent. There was no evidence of purulent meningitis or tubercle. This case occurred seven years ago At the present time I should have completed the operation by tapping the lateral ventricle and on finding excess of fluid might have established a permanent drain between the ventricular cavity and the subdural space, after the manner suggested by Dr Leonard Hill s researches and carried out by Dr Sutherland and Mr Watson Cheyne.

Posterior basal meningitis —The prominent symptoms of this condition are headache vomiting rigidity or contraction of the muscles of the back of the neck, leading to retraction of the head, and convulsions. Although the disease often runs a very chronic course optic neuritis is absent in the majority of cases (Barlow and Lees) The lesion consists, as a rule, in a serous or sero-purulent exudation at the posterior part of the base of the brain, the inferior surface of the pons and cerebellum, and the fourth ventricle. Internal hydrocephalus often results from matting of the membranes over the floor of the fourth ventricle and may be indicated in infants by bulging of the anterior fontanelle. The clinical details of this affection are well illustrated by the following case

Purulent otitis media complicated with chronic basal meningitis —A boy, aged 12 years, was admitted under the care of my colleague, Dr A. E Sansom, on March 27th 1897, with a history of headache, vomiting, and diarrhœa for 14 days. The vomiting continued every day except when he lay quite still, but the pain in the head was the chief trouble. The child was extremely apathetic and drowsy and the temperature was only slightly raised. On March 29th slight purulent discharge from the right ear was noticed, and a history of previous otorrhœa on the same side was obtained The extreme drowsiness, headache, and vomiting, with absence of pyrexia, suggested abscess of the brain There was no definite optic neuritis but the discs were a little pink and their margins were slightly blurred Operation was performed on April 3rd. The right mastoid antrum contained no pus, but there were suppuration of the middle ear and a perforation of the tegmen tympani The lateral sinus, temporo sphenoidal lobe and cerebellum were explored with a negative result A dura mater separator was also passed along the anterior surface of the petrous bone but no pus was evacuated He did not vomit again until the fourth day after the operation and then only occasionally, but the general condition did not improve. Later, rigidity of the muscles of the back of the neck, with retraction of the head, developed and on April 27th, six weeks after the commencement of his illness, it was noted that the slight changes in the discs previously recorded had developed into distinct double optic neuritis The temperature remained low, with occasional irregular rises, until April 22nd, when it became persistently high, and he died on May 2nd, seven weeks from the beginning of his illness

The necropsy showed suppurative meningitis limited to the posterior part of the base of the brain There is little doubt that the meningitis existed before the operation and that it was secondary to the ear disease. It was, perhaps, first of the serous type, and the persistent high temperature latterly may indicate the onset of suppuration.

Time will not permit me to discuss the pathology of posterior basal meningitis. You will recall that Barlow and Lees have shown that the infection in the majority of cases reaches the brain by means of the ear They suggest that in all cases the membrana tympani should be tapped in the early stage of the disease. If purulent otorrhœa be present it is quite clear that a complete mastoidectomy should be performed Attempts, for the most part unsuccessful, have been made to relieve the internal hydrocephalus often present in this affection by exposing and draining the floor of the fourth ventricle When marked intracranial pressure exists relief has been obtained by tapping the lateral ventricle.

Epidemic cerebro-spinal meningitis may closely resemble posterior basal meningitis due to ear disease In the former Kernig's sign is present and in the latter absent except in those cases in which the meningitis has extended to the cervical portion of the cord. Lumbar puncture in cerebro-spinal meningitis yields a large quantity of fluid in which the bacillus intracellularis may be demonstrated It should also be borne in mind that tuberculous meningitis with accidentally concurrent otorrhœa may easily be mistaken for meningitis due to septic ear disease. The following case so aptly illustrates this point that I will briefly quote it.

An infant aged six months, was admitted to the Evelina Hospital with purulent discharge from the right ear, general convulsions blurred discs, and complete paralysis of the right facial and of the right sixth nerves Later there was some retraction of the head It appeared probable that the facial nerve was paralysed owing to the ear disease and the sixth nerve from some basal meningitis Mastoidectomy was therefore performed and pus was found The membranes of the brain were incised At the necropsy there was a little lymph at the base of the brain, a mass of soft yellowish lymph in the right Sylvian fissure, and the lateral ventricles were distended. The paralysis of the sixth and seventh nerves was, however, due to a small tuberculous tumour on from St. Thomas's Hospital and the Hospital for Sick Children, Great Ormond street, by Acland and Ballance 11 were temporo-sphenoidal and 24 cerebellar In the first set of statistics, therefore, cerebral abscesses are twice as frequent as the cerebellar, and in the second set the reverse existed. Further, Körner's statistics show that cerebellar abscesses are rare before the age of 10 years and relatively common in the second and third decades, especially the former, whereas the statistics of the Hospital for Sick Children show that in six cases occurring during the last 35 years four were cerebellar and all the patients 10 years of age or under Two only were temporo-sphenoidal, the ages of the patients being 10 and 11 years. The statement generally accepted that abscess from ear disease is twice as frequent in the cerebrum as in the cerebellum therefore requires investigation if not revision.

In dealing with the diagnosis of the group of diseases just described it is only possible to fix upon types The lesions are often combined as shown by the cases related. A sinus thrombosis may be complicated with meningitis or with cerebral abscess, or again abscess with meningitis. The more striking and critical symptoms of meningitis will then predominate. Unfortunately, in many cases the conditions existing can only be arrived at by systematic exploration of the sinus meninges, temporo-sphenoidal lobe, and cerebellum. This procedure is usually the sequel to mastoidectomy and may be carried out by prolonging the mastoid opening backwards in the direction of the base line for a distance of an inch to an inch and a quarter behind the posterior margin of the meatus and then removing bone with Hofmann's forceps in a direction upwards and forwards to expose the temporo-sphenoidal lobe and downwards and backwards to expose the cerebellum. The presence of abscess is usually indicated by bulging of the dura mater with absence or diminution of pulsation. If nothing be found and symptoms of intracranial pressure exist, the operation should be completed by tapping the lateral ventricle with a fine trocar In those cases of abscess where localising symptoms are present the lesion may be approached by trephining directly over the abscess. It is of great importance to open the abscess freely and to remove by flushing the sloughs of brain tissue which are commonly present. In flushing the cavity due precautions should be taken to allow free exit for the fluid injected. More than one abscess cavity may exist or a second may form later

Let us give all honour to the pioneers in this department of surgery whose insight and enterprise have enabled us to treat these formerly fatal affections with something approaching satisfactory results. It remains for us to study in detail the fields which they have opened up

In conclusion, gentlemen, permit me to thank your council for the honour which it has conferred upon me in requesting me to deliver this lecture and yourselves for the indulgent attention which you have accorded to me.

A Lecture

ON

CHRONIC OBSTRUCTION OF THE CÆCUM AND ASCENDING COLON

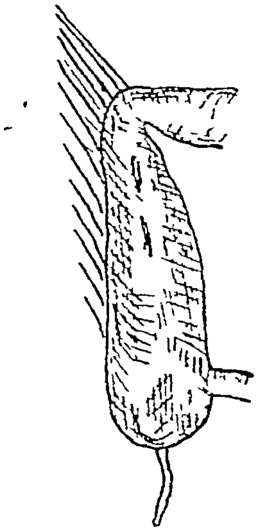
Delivered before the Sydenham Medical Society on Nov 20th 1902

BY W ARBUTHNOT LANE, M S LOND,
F R C S ENG.,
SURGEON TO GUY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN GREAT ORMOND-STREET

GENTLEMEN —In a paper published in the *Clinical Journal* of June 5th, 1901 entitled "Moveable Kidney" I drew attention for the first time to a condition of the cæcum and ascending colon which is not infrequently associated with moveable kidney and which results from chronic constipation. I make no apology for again calling attention to the matter since its recognition is of vital importance and the frequency of its occurrence is most striking Inflammation of the appendix is by no means an uncommon complication of the damming up of fæces in the cesspool of the intestinal tract produced either by fæcal matter being driven into the appendix or by obstruction to the free exit of its normal secretion which is probably formed in excess owing to its functions being exaggerated by the irritation or even inflammation of the cæcum and by swelling of its mucous membrane

The condition to which I wish to call attention is an interference with the free passage of the intestinal contents through the hepatic flexure. This practical obstruction is brought about by the development of a mesentery which is attached to the outer surface of the cæcum, ascending colon, and hepatic flexure Should the cæcum become at all distended its movement in an inward and upward direction brings about such a kink in the hepatic flexure as to render the passage of fæces through it exceedingly difficult and sometimes impossible, in which latter case it produces symptoms of acute intestinal obstruction It may occasionally happen that the cæcum passes sufficiently upwards and inwards to produce what is called a volvulus, rotation taking place around the general axis of the new mesentery and of the meso-cæcum and meso-colon. In order to render the description as clear as possible I have attempted to elucidate it by a diagram Fig 1 represents the cæcum, ascending colon, hepatic flexure, and commencement of the transverse colon The appendix and end of the ileum are seen The mesentery is indicated to the left of the cæcum by linear shading which represents the direction in which it exerts traction. The marks on the front of the ascending colon are bridles formed by the shortening up of the longitudinal fibres. These are so marked in some cases as to require to be partly divided in order to restore the colon and cæcum to their normal position and their capacity for performing their functions efficiently A little consideration of this state of affairs shows that the new mesentery is developed partly with the object of supporting the loaded cæcum in the erect posture of the trunk and partly to obviate its excessive inward displacement and the formation of a volvulus. The mesentery is strongest at its upper part where it is reflected from the surface of the posterior abdominal wall external to the kidney and from that organ as well. This relationship of the mesentery at its point of greatest traction to the kidney and the ilio-hypogastric, ilio-inguinal, and last dorsal nerves is one of considerable importance clinically Running in the mesentery are numbers of blood vessels some of which may be sufficiently large to require the application of a ligature before division. The examination of the connexion of the new mesentery with the large bowel explains how it is that in the recumbent position the obstruction produced by the kink is relatively small as compared to the mechanical disability which exists in the erect position and especially when the cæcum is loaded.

FIG 1



Represents the cæcum ascending colon hepatic flexure and commencement of the transverse colon

As one would expect the chronic obstruction of the flexure internal jugular vein was first tied and the clot was subsequently removed. The discharge ceased on the third day after the operation and his mental condition soon become normal but for a time the optic neuritis progressed. Flame shaped hæmorrhages, not present at the time of the operation, appeared in the right eye and later to a slight extent in the left. A fortnight after the operation (August 31st) the grasp of the left hand was still distinctly weaker than the right, showing that the paresis was not simply due to pressure downwards as Macewen suggests, but to encephalitis. When he had quite recovered from the first operation complete mastoidectomy was performed with success for the cure of his otorrhœa He returned to work and remained well for a time, but a year after the operation he was stated to be suffering from melancholia.

Macewen divides the phenomena accompanying abscess of the brain into three stages first, the initiatory stage, secondly, that of the fully formed abscess, and thirdly, the various terminations of the affection when uninterrupted by treatment. The above case was seen in the second period The first or initiatory period is rarely observed by the surgeon and therefore a reference to the following case which I watched throughout may be of interest.

On June 30th, 1898, I saw a girl, aged 14 years, with Dr Brodribb and Dr Christopherson Three weeks previously she went to the seaside suffering from tonsillitis which was followed by earache and otorrhœa on the right side. The temperature was at first of a septic type, but five or six days before I saw her it fell, varying between 97 5° and 100° F There was extreme pain on the right side of the head and for the last three days she had occasionally vomited, had also been drowsy, and on the 29th she became distinctly lethargic and only spoke when roused On the 30th the mastoid antrum was opened and was found to be much dilated and filled with pus. The sigmoid sinus was normal. On July 1st vomiting had ceased and there was distinctly less drowsiness She answered questions and conversed freely Her temperature was 100 5° On the 6th, as the discharge from the ear still continued to be profuse, the opening into the mastoid antrum was continued into the middle ear, the attic was exposed, and the ossicles were removed. On the 10th the patient's general condition was good, there was no headache or vomiting But on ophthalmoscopic examination the right disc was found to be distinctly swollen and striated. Slight blurring of the discs had previously been observed. On the 20th the temperature had been normal for the last five days. Her general condition was good and she got up On the 29th and 30th she was up and appeared to be quite recovered but on the 31st she was attacked with severe intermittent headache over the right occipital region and vomited several times Vomiting and paroxysmal exacerbations of severe pain continued and I saw her again on August 4th. There was neither paralysis nor alteration of sensation, the knee jerks were normal The optic neuritis had progressed and was marked on both sides She had also on one or two occasions had incontinence of urine and was wasting The temperature had been low since July 16th and the morning temperature was often 97 8°, but the pulse was 120 I operated again and found a large abscess in the right cerebellum From that time she rapidly recovered although, as in the former case, the optic neuritis progressed for a time but ultimately completely cleared up and in September of the same year I found that with suitable glasses her vision in each eye was $\frac{6}{6}$

In a third case, that of a girl aged 16 years with right otorrhœa, there were absolutely no localising signs The knee jerks were feeble and sensation was normal. It is remarkable that in this case the temperature varied from 101° to 103° F and just before the operation was 102° There was no vomiting, headache or lethargy, although she had one rigor the day before the operation The brain was explored owing to the existence of progressive optic neuritis, the patient being also evidently ill. A few drops of pus were let out from the right lateral lobe of the cerebellum This patient also recovered making four successive cases of cerebral abscess which terminated favourably

My first case of cerebellar abscess, however which occurred in 1896, died a month after the abscess was opened from the formation of another abscess in the neighbourhood of the first and meningitis. The relapse took place while I was away on my holiday and no attempt at further exploration of the brain was made. I am therefore able to record six cases of cerebral abscess, four of which recovered. One of the fatal cases was hopeless from the first owing to involvement of the lateral ventricle.

The typical symptoms of cerebellar abscess when localising signs exist are well illustrated by the first case related. The rotatory movements towards the opposite side were shown by the patient constantly turning in bed so that the side of the lesion was uppermost. The paresis of the upper extremity on the same side was also marked This is by no means a common symptom in cerebellar abscess, although in the past it may often have been overlooked. It was present in only one of my four cases Of 100 cases analysed by Acland and Ballance there was paralysis of the limbs on the same side five times and on the opposite side twice. In some instances there are muscular rigidity and convulsions on the same side. The upper extremity may be affected alone or together with the lower extremity, the latter being usually involved to a slighter degree. The knee-jerk is often exaggerated on the same side. Sensation is never affected.

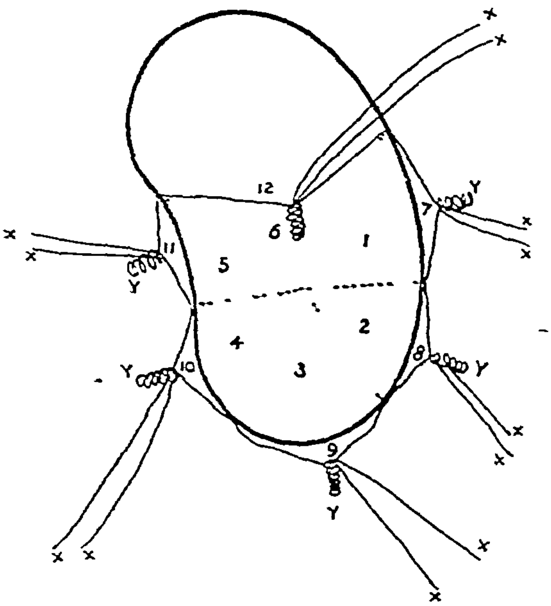
Some difference of opinion exists among experts as to the cause of the paresis The view generally entertained is that the cerebellum augments the power of movements originating in the cerebral hemisphere of the opposite side. This was suggested by Rolando and confirmed by Luciani, who terms the condition of the limbs parasthenia. After ablation of one half of the cerebellum, the prominent symptoms are weakness, tremor, and at first, spastic rigidity of the limbs on the same side, tremor of the muscles of the trunk and neck, and conjugate deviation of the eyes towards the opposite side. The animal falls towards the weakened side with the side of the lesion undermost. Further, the cerebellum is the organ which receives and reflexly acts on sensations derived by means of the "muscular sense," which supports the tonus and coördinates the innervation of the muscles of the skeleton It is the derangement of these functions which is mainly responsible for giddiness. Macewen, however, believes that the paralysis results from pressure exercised on the pyramidal tract after its decussation. He says "The normal cerebellum passes downwards beyond the foramen magnum, and, under pressure from the abscess, would probably extend further into the spinal canal so that the upper part of the cord may actually be pressed on" He also suggests that the paralysis occasionally observed on the side opposite to the lesion may be due to pressure by the abscess upon the pons on the same side.

Paralysis being rare in cerebellar abscess, it is therefore of great importance to watch for other indications. In the early stage vertigo and staggering may be noticed and the patient may fall to the side opposite to the lesion. Severe pain, often paroxysmal, is experienced over the corresponding occipital region Vomiting is intense and optic neuritis is usually present and well marked. There is often conjugate deviation of the eyes to the opposite side, it was noted in two of my cases In doubtful cases of abscess approaching the 'latent" variety the discs should be constantly watched and due weight must be given to emaciation and incontinence of urine These symptoms were of much value to us in deciding on an operation in the second case related.

It has been suggested by McBride that in cerebellar abscess septic organisms travel from the *internal* ear to the posterior surface of the petrous bone and thence to the cerebellum The labyrinth having been destroyed a tuning fork is not heard on the affected side, and this circumstance constitutes a diagnostic symptom of cerebellar abscess. There is, however, evidence to show that in some instances septic infection travels by means of the sigmoid sinus and thence to the cerebellum. In one of my four cases of cerebellar abscess there was suppuration around the sigmoid sinus and also thrombosis. Further in some cases recorded bone conduction was present. McBride's sign is therefore only of diagnostic value when bone conduction is absent. The presence of conduction does not exclude the cerebellum. Optic neuritis is more constant and marked in cerebellar than in temporo-sphenoidal abscess It is present in the former in 20 per cent of cases (Acland and Ballance) In neither of my cases of temporo sphenoidal abscess did any material change of the disc exist It has been stated that in cerebellar abscess the optic neuritis is more intense on the side of the abscess or is only present on that side. In two of my cases it was more intense on the same side and in a third on the opposite side.

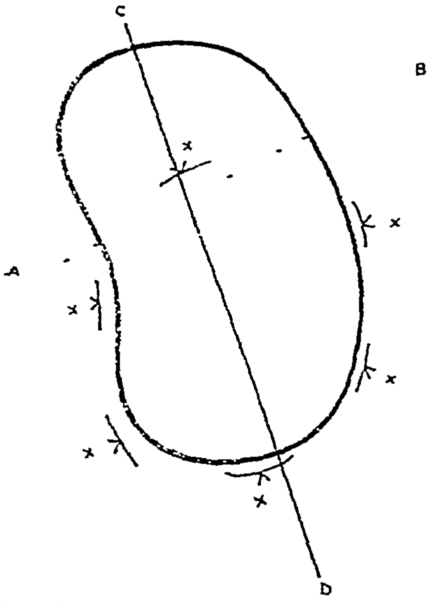
Statistics concerning the relative frequency of temporo-sphenoidal and cerebellar abscess are contradictory Of 91 cases collected by Körner 62 were cerebral and 29 cerebellar On the other hand, of 33 cases collected each is twisted up, when a piece of sterile silk twist is tied securely to it. The kidney is replaced within the abdomen in such a position that little more than half of it is exposed below the last rib Needles are placed on each silk thread and they are passed through the last intercostal space and through the abdominal muscles within an inch of their cut margins so as to bring the raw surface of kidney into apposition with the deep surface of the muscle wall freed from fat and fascia. When these sutures have been secured the resistance offered by the capsule is sufficient to require the expenditure of a considerable amount of force to displace the kidney from the position in which it is fixed. The incisions in the muscle wall and skin are then brought accurately together In this operation, as in every operative procedure requiring the burying of silk or other sutures, the surgeon should insure that no portion of ligature left in the wound be touched by the hand on any excuse whatever I have performed this operation a very large number of times and I have never known the kidney to move from its attachment to the wall. On two occasions I have subsequently had to expose such a kidney (*once to remove a stone*) and the kidney substance and muscle wall were observed to be most intimately united.

FIG 2



Represents the posterior surface of the kidney the dotted lines showing the triangular areas (1, 2, 3, 4 5 and 6) from which the segments of the capsule have been stripped (7 8, 9 10 11 and 12) These are shown with their bases continuous with the kidney and twisted—Y representing the twisted portions, a silk suture (X) being attached to each.

FIG 3.



Represents the conditions present after the incision through the muscular wall has been closed. The incision is indicated by the firm line C D crossing the kidney from above downwards and outwards. The dotted line A, B shows the margin of the thorax. The several sutures X, connecting the capsular segments to the muscle wall, are seen emerging from it and tied securely

When I have found any considerable hydro-nephrosis resulting from excessive mobility or from other cause I have employed a method which has been more successful than I ever ventured to expect. It has enabled me to save a number of kidneys which would in the ordinary course of events have been excised. I am strongly of opinion that the operation of excision of the hydro-nephrotic kidney has been undertaken much too frequently and often unnecessarily I do not think that we should resort to such a serious measure until we have tried every other means possible to save the organ, following the same general principles that guide us in operations elsewhere.

The procedure I adopt consists in exposing the hydronephrotic kidney with its pelvis and a considerable length of the ureter by a very long oblique lumbar incision, defining its mode of entry into the dilated pelvis. If any vessel is present in this situation over which the ureter is hitched it is ligatured and divided, but such as a real cause of obstruction is in my experience very rare. An incision is made along the outer margin of the kidney into the dilated pelvis and if possible a fine gum elastic catheter is introduced through it into the ureter along which it is passed beyond the brim of the true pelvis. In most cases I have found it impossible to introduce the catheter into the ureter in this way, so I have opened the ureter by a vertical incision and passed the catheter through it into the pelvis of the kidney and out through the incision in this organ. The end of the catheter being in the ureter it is forced down beyond the incision in its wall for a considerable distance, when the opening in the ureter is accurately closed by means of a fine silk suture. The incision in the kidney is sutured, a piece of drainage tube being left in the pelvis and this, with the catheter projects through the skin incision. The catheter is left in the ureter for six weeks or two months, during which time urotropin and sandal-wood oil are freely administered By the use of these drugs the urine remains normal and the catheter does not become incrusted with any deposits of salts on its surface, but is perfectly sweet and clean when removed at the end of this time. The drainage-tube is taken away a few days later and the wound is closed.

SOME OBSERVATIONS ON CYANOSIS[1]

BY G A. GIBSON, M.D , D SC , F R.C P EDIN ,
PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH.

THE one constant factor in the production of cyanosis is diminution of oxygenation This may be the result of respiratory affections which hinder the access of air or diminish the area of the aerating surface, or it may, on the other hand, be due to circulatory disorders lessening the amount of the blood flowing to the lungs. These latter affections furnish the most conspicuous examples of cyanosis, and in them the symptom is entirely produced by hindrance to the blood flow Such is in reality the original conception advanced by Morgagni[2] and supported by numerous *observers. The other view* apparently suggested by Corvisart[3] that the condition is due to admixture of arterial and venous blood, is absolutely untenable, as *in the* vast majority of cases there is no possibility of such intermingling In general terms the blood in cyanosis may be said results in a progressive distension and hypertrophy of the cæcum. Because of the intimate fixation of the colon to the kidney and to the abdominal wall outside it and to the nerves in that situation the pain felt along the distribution of these nerves and the tenderness on pressure below the last rib may be more typically renal in character than they are in the case of stone in that organ Before I recognised this condition I, like many others had frequently cut down upon the right kidney, which had given all the symptoms of stone except blood in the urine, and had been disappointed to find nothing although the kidney had been effectually cleared and its interior and the ureter thoroughly examined. One was however, puzzled, and also not a little pleased to find that after this operation the patient usually lost all or most of the pain and that this more or less complete freedom from pain continued in some cases indefinitely In a number of instances it recurred after an interval of time From a careful study of these apparently renal cases it became obvious that the symptoms were due to obstruction of the colon by adhesions and not to any affection of the kidney and that the freeing of the kidney from its surroundings released the tense omentum from its posterior attachment and helped to relax the kink in the colon by displacing the peritoneal adhesions from the posterior abdominal wall Thus the operation unwittingly restored to the colon greater freedom to the passage of its contents Later, if constipation still continued the adhesions reformed and again drew upon the flexure and the pain and mechanical disability returned

---

[1] Abstract of a paper read before the Royal Society of Edinburgh on Dec. 15th, 1902.

[2] De Sedibus et Causis Morborum, tome 1 p. 154 1762.

[3] Maladies du Cœur p. 231, 1806.

I am certain that in a large proportion of cases of so called appendicitis the primary factor in the production of inflammation of this structure is obstruction of the hepatic flexure producing the consequences which I have just now described and that the trouble in the appendix is merely a secondary manifestation and should be treated as such should operative measures be adopted. This explains the occurrence of appendicitis in cases of recurring or chronic constipation and the advantage that is very frequently gained from emptying the cæcum by free purgation on the first onset of trouble about the appendix It also shows the cause of the pain which so often remains after the mere removal of an appendix and the necessity not only of excising a diseased appendix but also of dividing freely the mesentery and liberating the hepatic flexure which in these cases is bound down into the upper and back part of the abdominal cavity It is, therefore quite evident that in removing the appendix the surgeon too often carries out only a portion of the necessary surgical procedure. In not a few cases the surgeon removes an appendix which is apparently quite normal and he satisfies himself as to the justifiability of the operation by believing that between attacks the appendix may be perfectly healthy I do not say that this may not uncommonly be the case, but when it is it indicates that the trouble is due chiefly to the obstruction at the hepatic flexure which should be treated medically or surgically, and that excision of the appendix itself is unnecessary and of the nature of a luxury I am convinced that a considerable proportion of cases in which the patient complains of pain and tenderness in the right iliac region are not appendical at all, but come under the category of those indicated by the title of this paper

The symptoms which result from obstruction at the hepatic flexure vary within very wide limits While in one extreme complete acute intestinal obstruction may result occasionally complicated by the twisting of the colon upon the new mesentery forming a volvulus, in the other extreme we have cases with pain or uncomfortable sensation along the last dorsal, ilio-hypogastric, and ilio-inguinal nerves with dragging in the loin and tenderness on pressure or on percussion immediately below the last rib posteriorly and variable tenderness on pressure over the cæcum which may be felt to be full and its walls to be thickened. Occasionally the patient complains of some disturbance of the bladder in the onset of an attack of pain. These symptoms all suggest some renal trouble In other cases the patient complains of much fulness and distension of the cæcal region often accompanied by a considerable amount of tenderness, rendering it impossible to bear pressure or to wear any tight garment in that situation. Or, again, the attacks of pain and tenderness may be so severe as to be associated with vomiting The assumption of the recumbent posture and free purgation generally relieve them The cæcum is left sore and tender for some time after the attack and this is associated with much disturbance of the gastro-intestinal tract. This condition may recur at intervals for many years and I have operated for it in patients of advanced years whose life had been made uncomfortable for a very long period of time and who obtained complete relief from the freeing of the anchored flexure. Some of them had been regarded as suffering from some appendical lesion and operation for the removal of this structure had been advised. Any of these conditions may be complicated by an attack of inflammation of the appendix. I have frequently had to operate upon patients in whom the appendix, either inflamed or not, had been removed without benefit to the sufferer, and I have found the hepatic flexure obstructed in the manner described and have divided the mesentery and freed the hepatic flexure and have permanently relieved the patient of the painful symptoms. Again, I have operated on cases and found this condition to exist where the symptoms were ascribed by competent observers to disease of the appendix which was perfectly healthy If what I have observed be true the habit that has recently cropped up of removing the appendix through a very small incision must be injudicious in the extreme.

Before leaving this subject I would call attention to the symptoms of moveable kidney which not infrequently exist in patients suffering from a practical obstruction of the hepatic flexure In such cases some difficulty may be experienced in determining whether the mobility of the kidney or the distension of the cæcum forms the chief source of the patient's symptoms since the kidney when it gets upon the front of the innominate bone produces symptoms of pain and tenderness in the iliac fossa with dragging in the loin and occasional attacks due to obstruction to the exit of urine from it, symptoms which sometimes closely resemble those due to obstruction of the hepatic flexure. When both conditions co exist it is sometimes hard to decide which should be treated first or whether both demand the attention of the surgeon. If the kidney is suffering materially in the performance of its functions from any surgical cause whatever there is associated with it a tenderness of the ureter which can be most readily observed where this duct crosses the brim of the pelvis This symptom I have found to be of the greatest possible service in helping one to determine whether the condition was primarily or chiefly renal or not It is such a marked characteristic that I have known cases in which surgeons have removed the appendix because the patient complained of a narrow tract of great tenderness when pressure was exerted on the abdominal wall in a line extending from the umbilicus to the anterior superior iliac spine, which is commonly called McBurney's line. I have known these patients to obtain no relief from their symptoms in consequence of this operation, their troubles returning during convalescence as soon as they ceased to assume the recumbent posture. In such cases I have sewn up the kidney which was moveable and given them permanent relief from their painful symptoms I believe that this tenderness of the ureter which is associated very commonly with moveable kidney is responsible for many appendical operations But I have never seen it called attention to before in this relationship and I would ask surgeons to consider the point more carefully in future before deciding to open an abdomen merely because the patient complains of great local tenderness when manipulation is made in this situation.

Since I first devised the operation for employing the capsule to fix the kidney immoveably to the posterior wall of the abdomen, which I described in the Transactions of the Clinical Society for 1892 in a paper entitled "A Case of Floating Kidney treated by a New Mode of Nephrorrhaphy," I have operated upon a very large number of cases of moveable kidney and in no single case have I known this organ to break away from its mooring Up to that time the operation which had been adopted was to fix the kidney by buried sutures passed through its substance and the results of such treatment were openly acknowledged by very experienced surgeons to be unsatisfactory and uncertain in the extreme. Previously it had been the custom to use temporary sutures. I had myself examined many cases in which this operation had been performed without its materially affecting the mobility of the organ

The method I described, and which I still employ, is the following The kidney is thoroughly exposed through a slightly oblique incision in the loin and freed from any fat that may be present. As it projects from the wound the capsule is stripped from its lower two thirds in the form of six triangles as shown in Fig 2, the bases of the triangles being left intact. In order to increase its resisting capacity the whole system can, for the future, be regarded as of scientific value

The final part of this preliminary inquiry has been devoted to an attempt to ascertain whether the inhalation of oxygen has any beneficial effect upon cyanotic conditions Up to the present time it must be confessed that no case which has been under my care has shown any effect upon the blood from the use of this method. Of the cases which have been so treated the following two may be taken as types of all the others.

CASE 3.—A miner, aged 39 years has recently been under my care on account of chronic bronchitis, emphysema, and pulmonary collapse, with great displacement of the heart to the right side He was deeply cyanosed and had clubbing of the fingers and arching of the nails. The heart was slightly enlarged and two thirds of its dulness lay to the right of the mid sternal line. A tricuspid systolic murmur was present The pulse was frequent, varying between 80 and 100 and was of low pressure. There were anasarca with great enlargement of the liver and considerable enlargement of the spleen, as well as albuminuria. On Oct. 20th, 1902, the hæmoglobin was 110 per cent., the red corpuscles numbered 6 400 000 and the white 12,500 per cubic millimetre. On the 26th the hæmoglobin was 112 per cent., the red corpuscles numbered 7,500,000 and the white 14,000 per cubic millimetre On this date the inhalation of oxygen was begun and on the 31st, five days later, the hæmoglobin was 100 per cent while the red and white corpuscles numbered respectively 8,000,000 and 9960 per cubic millimetre.

CASE 4 —A miner aged 33 years, came under my care on account of mitral obstruction and incompetence. He suffered much from palpitation. His heart was slightly enlarged There were presystolic and systolic mitral murmurs and the pulse was of very low pressure with considerable irregularity There were no changes in the respiratory system. The abdominal organs were unchanged and there was no albuminuria. The condition of the blood may be stated in tabular form as follows —

	Hæmoglobin. Per cent	Erythrocytes Per c.m.	Leucocytes Per c.m.
Oct. 20th	131	7,500 000	11 400
31st	120	7 000 000	9 680
Nov 17th	110	7,250 000	10 000
Dec. 3rd	110	6,500 000	11 000

On Dec. 3rd oxygen inhalation was begun.

Dec. 5th	115	7,400 000	9 800
8th	110	6,000 000	10 000

The results of these two observations seem to indicate that the inhalation of oxygen is barren of result. It is generally understood that the ordinary air of the atmosphere contains considerably more oxygen than can be absorbed in any circumstances, and the results of our observations, now fairly numerous, are strongly in favour of this conception.

It is a pleasure to express my warm thanks to my house physicians, Dr L O Peel Ritchie Dr H. H Bullmore, and Dr A. F R. Conder for their unwearied devotion in conducting the examinations of the blood of many patients in pursuance of these observations, and to acknowledge the assistance which we have received in our investigations from Dr. A. Goodall and Dr A. Dingwall Fordyce.

Edinburgh.

TWO CASES OF CÆSAREAN SECTION FOR OBSTRUCTION DUE TO FIBROID TUMOURS

BY ARTHUR H. N LEWERS, M.D , F R.C P LOND ,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

IN the majority of cases in which fibroid tumours complicate pregnancy no special treatment is required. The course of pregnancy is unaffected labour occurs naturally, and no unfavourable symptoms arise during the puerperium. In a certain relatively small proportion of cases however, the presence of a fibroid tumour or tumours in association with pregnancy constitutes a serious danger both to mother and child. Thus in the early months the patient may experience such severe pain that all expectation of allowing the pregnancy to continue has to be abandoned. In some cases the pain is due to the impaction of a pedunculated subperitoneal fibroid in the pelvis, and in some such cases it is possible without undue force to push up the fibroid with relief of the symptoms. In addition to the pain difficulty in micturition is very apt to occur, and this was, in fact, among the symptoms at the fourth month in Case 1 recorded below While undoubtedly pain may be so severe as to require the interruption of the pregnancy it is well not to accept this view of the matter hastily In both cases recorded in this paper pain was a marked symptom at about the fourth month, yet in both of them the pain did not long continue severe and it disappeared altogether in the course of a few weeks It should also be borne in mind that in many of these cases of fibroid tumour complicating pregnancy the patients are women pregnant for the first time and that, apart altogether from the presence of fibroids, many such patients have what appears to them to be severe pain, due no doubt to stretching of the various tissues, for instance, to stretching of the abdominal walls Thus some allowance has to be made for this Again, it is generally held that fibroids coexisting with pregnancy predispose the patient to miscarry I am inclined myself to believe that this is so, but probably much depends on the exact position of the tumour However this may be, in a recent case of the kind in my practice, where a miscarriage occurred at about the middle period of pregnancy, there was very severe post-partum hæmorrhage.

The effect of fibroid tumours on the process of labour is generally little or nothing unless the fibroid is so situated as to constitute a serious or even insuperable obstacle to the passage of the child After labour there is a considerable risk of septicæmia if the fibroid has been damaged during the process of delivery In both the cases here recorded the position and size of the fibroid were such as to render delivery of a living child by the natural passages out of the question. In both cases it happened that I saw the patients at about the same period of pregnancy—viz., about the fourth month—so that several alternative methods of treatment were possible.

1 Thus in the first place, the pregnancy might have been terminated either by the induction of a miscarriage or by abdominal hysterectomy In both cases though it would have been possible to induce a miscarriage, as the vaginal portion of the cervix was in each case even then displaced high up and to the left the necessary manipulations would have been none too easy If some portion of the placenta had been retained, as would not have been unlikely, it would have been an extremely difficult thing to remove it. By this treatment, too the child would of course have been sacrificed. For all these reasons I considered the induction of a miscarriage unsuitable for either case. Had it been really necessary to terminate the pregnancy either on account of pain or for any other reason I think that abdominal hysterectomy would have been the better treatment Mr Alban H. G Doran recently[1] published an interesting paper recording three cases of fibroids complicating pregnancy in which he performed abdominal hysterectomy in the middle period of pregnancy In neither of my cases, however, did there seem to be any sufficient reason for interfering, though when I first saw the patients they were suffering from a good deal of pain. This soon diminished and before long entirely disappeared. In each case the remainder of the pregnancy was quite normal.

2. An attempt might have been made to remove the tumour by myomectomy, leaving the uterus in the hope that the pregnancy would continue undisturbed. As regards the first case there was a large fixed tumour lying to the right of the cervix. It evidently lay in the broad ligament. In the second case the tumour sprang from the supra vaginal cervix and had grown down into the recto vaginal septum, displacing the vaginal portion of the cervix upwards and to the left. The mechanical difficulty of getting at a tumour so low down without removing the uterus would have been very great. In some cases of myomectomy during pregnancy, even when the 'bed" from which the tumour has been enucleated has been fairly accessible it has been found necessary to remove the uterus before the bleeding could be controlled This seemed still more likely to happen in my cases if myomectomy had been attempted, on account of the low position in the pelvis occupied by the tumour in each case. I therefore decided against myomectomy

---

[1] THE LANCET Nov 29th 1902, p 1451

to be of high specific gravity—from 1070 to 1080 The amount of hæmoglobin rises considerably—often reaching above 100 per cent The erythrocytes increase in number so as frequently to exceed 7,500,000 per cubic millimetre, while the leucocytes, although not so commonly altered in number, often reach such a figure as 12,000 per cubic millimetre. The increase of these constituents of the blood was first observed by Toeniessen.[4] Malassez[5] showed that there are more red corpuscles in the blood of the superficial than of the deeper parts of the body Toeniessen and Penzoldt[6] suggested that this might be due to loss of fluid from the surface, while the interior receives a constant supply of fluid from the alimentary tract. Eight years ago, in describing some observations on the Cyanosis of Congenital Heart Disease in THE LANCET,[7] an explanation of the manner in which cyanosis is produced was advanced by me. From that paper it seems advisable to quote the hypothesis to which my observations led me —

> Starting with the conception that cyanosis is produced by obstruction to the circulation and venous stasis the question now arises why this condition should be associated with an increase in the number of the blood-corpuscles It is not only in the cyanosis of congenital lesions that the increase is found but in all cases where cyanosis is really present on account of failure of the circulation To this point Toeniessen and Schneider have particularly called attention and of the accuracy of the observation anyone can convince himself by investigation of the blood The work of Malassez seems to show that the blood in the superficial parts of the body contains a larger number of red corpuscles than that from the deeper layers and Penzoldt and Toeniessen believe that this increase is caused by the loss of fluid from the surface while the blood of the interior is constantly receiving fluid from the alimentary canal Even if this be correct it cannot be accepted as an explanation of the great increase in the number of the corpuscles found in cyanosis as it would involve the postulate that in some cases where the number of corpuscles is nearly doubled the quantity of the fluids of the blood must be reduced nearly to one-half Cohnheim's celebrated experiment of tying the crural vein of the frog which is followed by a considerable increase of the corpuscles in the vessels with the transudation of serum into the surrounding tissues may be regarded as an explanation of the moderate increase in the cases accompanied by anasarca but it has no special bearing upon cases of congenital cyanosis in which there is no drain of fluid into the tissues It may possibly be held that in such cases the lymph vessels are unusually active and that the fluid constituents of the blood are as rapidly absorbed as they transude Such an opinion can scarcely be seriously entertained The backward pressure on the venous system which causes the transudation must tell on both terminations of the absorbents It may be admitted freely that the increased pressure on the peripheral veins may tend to raise that impelling the fluids into the commencement of the lymphatics, but it must not be forgotten that an elevation of pressure in the great veins will hinder the return of the lymph by pressing upon the openings of the lymph vessels into the veins It is probable that the increase in the red corpuscles may be to some extent compensatory in cases of cyanosis To say this however is not enough it affords no rational explanation of the process by which the increase is brought about. Nature does not work by such direct methods as would require to be invoked if the increase of the corpuscles were regarded as a simple compensatory change balancing the diminished power of oxygenation Compensation in valvular lesions for example, is produced by the definite structural changes constituting hypertrophy caused by increase of work and compensation in cyanosis must have some reasonable explanation also It seems to me that such an explanation may be found in a consideration of the functions of the red corpuscles under changed conditions. In venous stasis the corpuscles are insufficiently oxygenated they cannot perform such an active part as oxygen carriers and they cannot yield so much oxygen to the tissues It must further be remembered that in cyanosis there is less metabolism in the tissues and therefore less waste produced In a word, the functions of the corpuscles being lessened the tear and wear which they undergo is reduced and the duration of their individual existence increased The number of the corpuscles must in this way be proportionately augmented and this must lead to the numerical increase, as well as to the high percentage of hæmoglobin until a balance is struck between the production and the destruction of the blood-corpuscles

In some subsequent remarks upon this subject[8] it was frankly stated that this explanation could only be seriously entertained if the increase in the blood elements was found to exist throughout the different divisions of the circulatory mechanism—arteries, capillaries, and veins—but that the observations of many workers on the state of the blood in high altitudes were strongly in support of it.

The object of the present communication is two-fold in the first place to show what relationship exists between the conditions of the blood in the different divisions of the circulatory apparatus, and, in the second place, to indicate the results which have been obtained by the use of oxygen in cases of cyanosis. The two following cases are of interest from the first point of view

CASE 1.—A tradesman, aged 48 years, was under treatment in my ward for arterio sclerosis with interstitial myocarditis. He was very cyanotic The heart was considerably enlarged and there was escape at both mitral and tricuspid orifices. The radial arteries, like those throughout the rest of the body, were rigid, but the pressure was not high There were œdema of the lungs and albuminuria, with great anasarca. The patient became maniacal and then passed into a comatose condition from which he was rescued by venesection. The opportunity was taken of obtaining two or three drops of arterial blood and the condition of matters was as follows Artery hæmoglobin, 125 per cent., erythrocytes 5 130,000, and leucocytes, 5980 per cubic millimetre Vein hæmoglobin 135 per cent, erythrocytes, 5 300,000, and leucocytes, 6250 per cubic millimetre On the following day another drop of arterial blood was obtained and compared with that from the subcutaneous capillaries The results were the following Artery hæmoglobin, 120 per cent., erythrocytes 5,268 000, and leucocytes, 6100 per cubic millimetre Capillary hæmoglobin, 130 per cent., erythrocytes, 6 830 000, and leucocytes, 11,620 per cubic millimetre. After this blood letting the patient, by means of various cardiac remedies rapidly recovered and went home in a few weeks with no symptoms of circulatory disorder and with blood practically normal.

CASE 2.—A pithead boy, aged 16 years, is at present under treatment in my ward for a group of symptoms which seem only explicable by the diagnosis of mediastinal pericarditis On admission in September, 1902, the boy was deeply cyanosed. His heart was but slightly enlarged and had no abnormal sounds The pulse was of low pressure and manifested in the most beautiful manner the features of the pulsus paradoxus The patient had enormous enlargement of the liver and considerable increase in the size of the spleen, along with hydrothorax, ascites, albuminuria, and anasarca The subcutaneous blood was frequently and regularly examined and showed an amount of hæmoglobin varying between 80 and 100 per cent while the number of red corpuscles fluctuated between 8,000,000 and 8,600,000 per cubic millimetre and the number of white corpuscles oscillated between 5000 and 8500 per cubic millimetre. On Oct. 20th a drop of blood was obtained from a small twig of the temporal artery and another from a small tributary of the temporal vein in order to compare with the blood in the capillaries, and the following results were obtained. Artery hæmoglobin, 93 per cent., erythrocytes, 7 000,000, and leucocytes, 6875 per cubic millimetre. Capillary hæmoglobin, 93 per cent., erythrocytes, 8 500,000, and leucocytes, 8500 per cubic millimetre Vein hæmoglobin, 115 per cent, erythrocytes 10,000,000, and leucocytes, 7400 per cubic millimetre Under treatment by means of hydriodic acid, cardiac tonics, and diuretics internally, along with inunction of diluted lead iodide of mercury ointment, the patient has improved very greatly and although the liver and spleen are still enlarged the other symptoms have almost entirely disappeared Along with the disappearance of the symptoms the condition of the blood has come back practically to normal

Now we learn from these observations that in cyanosis there is a general increase throughout the whole circulation in the amount of hæmoglobin and in the number of the erythrocytes, while the state of matters as regards the leucocytes is less constant. It seems to me that this universal, if not uniform, increase goes a long way in support of the explanation which I ventured to advance in the paper to which reference has already been made. The whole subject, however, requires experimental investigation and it was my intention to have entered upon a series of experiments—an intention which has been frustrated by lack of time. One of my friends has undertaken a research upon the subject and it is to be hoped that in the course of a few months definite information will be available It is probable that the universally recognised increase in the number of the hæmocytes in those who live in high altitudes may be found to furnish an available opportunity of working out the problem.

Another point arises from the consideration of these observations. It has been said that the increase in the hæmoglobin and erythrocytes is universal but not uniform, and in this interesting fact lies the exposure of a possible source of fallacy in attempting to estimate blood conditions. No method based upon the assumption that the condition of the blood obtained from one part of the body can be regarded as an expression of its exact conditions throughout fœtal heart sounds The breasts looked active but no fluid could be squeezed out of them. On vaginal examination a catheter was first passed and the bladder emptied. The vaginal portion of the cervix was felt high up behind the pubes. The finger only reached it with some difficulty The os was not, however, directed upwards. A firm hard, fixed mass was felt in the posterior fornix, extending from the highest point of the posterior fornix some two inches or more downwards under the posterior vaginal wall It had a considerable measurement transversely and so gave the impression that the mass was somewhat muffin shaped The examination suggested that the tumour had grown from the supra vaginal cervix and that it had extended downwards between the posterior vaginal wall and the rectum It will be seen that there was as yet no certain evidence of pregnancy but that the physical signs made one almost certain that the patient was really about four months pregnant. It was quite certain that if this were so the solid fixed mass in the pelvis would absolutely prevent delivery of a living child. I gave it as my opinion that the patient was probably pregnant and advised that she should come and see me again in two months' time to make quite certain on this point I also advised that if she were pregnant the best course would be to allow pregnancy to continue till within a few days of full term and that Cæsarean section should then be performed. After having given my opinion I heard for the first time that the patient had seen two other obstetric physicians, one of whom, Sir John Williams, had advised the patient to wait, and the other had advised the patient to have an immediate operation for the removal of the tumour As the patient had then two opinions in favour of waiting against one in favour of immediate operation both she and her husband decided to wait.

[8] Diseases of the Heart and Aorta, p 211 1898

On August 1st I saw the patient again The pains of which she had previously complained about the lower part of the abdomen and back had disappeared She said that she had become much larger in the abdomen and was very well in herself, but said that she suffered from heartburn rather badly On examination the swelling in the abdomen had reached well above the umbilicus and I felt fœtal movements in it, but I did not happen to be able to hear the fœtal heart On vaginal examination the vaginal portion of the cervix was much higher up than at the previous examination and it was almost impossible to reach it. The hard swelling felt in the posterior vaginal wall was very much as before—perhaps somewhat larger The most probable date for labour to begin was Nov 16th.

It was arranged that the patient should go into a nursing home on Nov 3rd and that Cæsarean section should be performed on the 8th unless labour came on spontaneously in the meantime. This arrangement was exactly adhered to. I examined the patient when she was in the home on Nov 5th. It was then quite impossible to reach the cervix on vaginal examination The tumour was a great deal larger than at the time of the last examination The patient's general condition was quite good

On Nov 8th I performed Cæsarean section at 10 A M Dr F W Hewitt gave the anæsthetic and Dr Gow kindly assisted me at the operation. The uterus was opened by the usual longitudinal incision and the membranes ruptured, a leg of the child was seized and delivery rapidly effected The child, a male, was alive and soon cried loudly He was subsequently found to weigh 6 pounds 8 ounces After removing the placenta and membranes completely it was found impossible to find the opening of the internal os uteri. I tried several times to feel it in various directions without success and Dr Gow also tried but it was evident that the internal os was not at all dilated and we were unable to find it. After we had tried with the finger to find the opening I tried with a long coarse probe but was quite unable to locate it. We therefore decided not to trouble any more about it We thought an opening must be there and hoped that it would be large enough to allow the lochia to escape. The uterine wound was then stitched up as rapidly as possible with the usual deep sutures, avoiding the mucous surface, and numerous superficial sutures, taking the peritoneum and superficial layer of muscle only The sutures used for the uterus were as in the preceding case, of silkworm gut. At the lower end of the uterine incision the rather looser subperitoneal tissue had been slightly encroached upon. This led to a fair amount of effusion of blood immediately under the peritoneum, in the neighbourhood of the lowest two or three peritoneal sutures. An attempt was then made to prevent future conception. A loop of the right Fallopian tube was pinched up and tied, and the convex part of the loop cut off. It was then found that the uterus was so twisted on itself that though the right uterine appendages were very easily accessible the left lay deep down. The left ovary was felt close to the pelvic brim and the left Fallopian tube was tightly on the stretch, so that it lay closely applied to the surface of the uterus It would have been impossible to cut out a piece of the left Fallopian tube without very much enlarging the abdominal incision and it seemed to me unjustifiable to spend the further time that this would have required. The patient had been married ten years without being pregnant, a portion of the right tube had been already removed and the probability that she would become pregnant again seemed not very great and I decided to close the abdominal wound. Before closing the abdominal wound the relations of the tumour were carefully examined from above. On investigating the relations of the tumour with the hand, it was evidently, as had been thought, a fibroid growing from the supra vaginal cervix and extending down between the peritoneum and vagina and lower again between the vaginal wall and the rectum. I then closed the abdominal wound. After the dressing had been applied the patient's knees were held up in the lithotomy position It was then found that there was some blood in the vagina and externally, showing that the internal os was at all events open to some extent, it was not sealed over With the patient in this position it was possible now just to reach the vaginal portion of the cervix, still very high up. The external os was not in the least patulous, no more open than it had been when I first examined her in June. The patient was put back to bed

The subsequent progress of the case was very satisfactory From Nov 8th to 20th the temperature generally was in the neighbourhood of 100° at night, falling to normal in the morning On the 15th and the 17th respectively the temperature was 101 2° and 101 4° the highest points reached. The pulse rate was never over 100 and generally about 90 during this time After the 20th the temperature was below 100°, except on the 26th, when it reached 100 4° After that it never exceeded 99 4° till Dec 6th, when the patient went home. As regards the lochial discharge it was not at all profuse. At the same time it seemed about the average in quantity and it was not necessary to undertake any dilatation of the cervix to facilitate the outflow of the discharge. This was a point which gave me some anxiety till the course of events showed that there was no need for interference. For instance, if it had been necessary to wash out the uterus, it would have been quite impossible to do so without first dilating the cervix under an anæsthetic. Fortunately it was not found necessary to undertake anything of the kind. The mother did not suckle the baby, and at the end of a fortnight it was sent away from the nursing home with the monthly nurse to stay with some relations contrary to my advice, owing to the severe weather prevailing at the time However, no harm resulted, and at the time when the mother left the nursing home (Dec 6th) the baby was quite well.

Harley-street W

DIFFUSE CARCINOMATOSIS OF THE STOMACH AND INTESTINES

BY A. W NUTHALL, F R C S ENG,
RESIDENT SURGICAL OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM;
AND
J G EMANUEL, M.D, B S., B Sc., M R C P LOND,
PATHOLOGIST TO THE GENERAL HOSPITAL, BIRMINGHAM.

WE have recently had an opportunity of examining three cases of widely diffused malignant disease of the stomach and intestines, a condition which, so far as we have been able to ascertain, has not been previously described. In all the cases a long tract of the alimentary canal was affected, the stomach and the small and large intestines being in each case the seat of a widely diffused carcinomatous infiltration. In every case the stomach presented the condition described as "leather bottle stomach," either in whole or in part. Thus in Cases 2 and 3 the stomach was

3. Another alternative was to allow the pregnancy to continue till within a few days of full term and then to perform Cæsarean section This was, in fact, the treatment adopted in both cases One question remained for consideration—viz, whether conservative Cæsarean section should be the operation or whether after delivery of the child hysterectomy should be performed. It seemed to me that as in both cases the tumour had caused no trouble till pregnancy began there was a considerable probability that after involution of the uterus was complete no further trouble would arise. If subsequently symptoms severe enough to justify hysterectomy should occur it seemed to me that it would be time enough then to perform the operation. By the conservative Cæsarean section the uterus would be retained and the menstrual function would continue as before Other things being equal this seems to be a not unimportant argument in favour of performing the conservative operation rather than hysterectomy In Dr A Donald's[3] valuable paper on Fibroid Tumours complicating Pregnancy and Labour it is said that "when Cæsarean section has to be performed, as a general rule, it should be followed by hysterectomy The presence of a fibroid renders the risks of the conservative operation greater while at the same time it affords a distinct indication for the removal of the uterus." I have already given above the reasons which led me to perform the conservative Cæsarean section in my two cases *rather than Cæsarean section followed by hysterectomy* I think that in deciding much depends on the details of the particular case If, for instance, there are several large fibroids present and if there is a distinct history that the patient has previously to the pregnancy suffered a good deal from symptoms referable to them, then the Cæsarean section should be followed by hysterectomy On the other hand, when there is apparently only one fibroid, when it seems to be only of importance as an obstacle to delivery, having caused no trouble antecedent to the pregnancy, then I think the uterus should be left

CASE 1.—On Jan. 9th, 1902 I was asked by Mr H Richardson to see a patient who gave the following history She was 42 years of age and she had been married on May 20th, 1901 She had last menstruated in the second week of September, the 10th was the last day of the period She was taken ill on Dec. 20th, 1901, with great pain in the lower abdomen and difficulty in passing urine. The temperature at that time rose to 101° F She remained in bed from that time until the date when I was asked to see her On examining the abdomen an elastic swelling was felt rising out of the pelvis and reaching rather above the level of the umbilicus. This swelling lay somewhat to the left of the middle line. A hard lump was felt just above the pubes and to the right, separated by an indistinct depression from the elastic swelling above mentioned. Nothing was heard on auscultation over either swelling The breasts looked rather active On vaginal examination the vaginal portion of the cervix was found to be very high up and to the left. A hard swelling with the convexity downwards was felt in the right lateral fornix. It was nearly fixed and bimanually could be felt to be continuous with the hard lump felt above the pubes while examining the abdomen. The vaginal cervix had evidently been pushed upwards and to the left by this hard swelling It was difficult to estimate the size of this hard swelling exactly, but it appeared at this time to be of about the size of a large orange Although I had not obtained ballottement, and it was rather too soon to expect the fœtal heart to be audible, I had little doubt that the patient was about four months' pregnant. It appeared to me that the elastic swelling described as lying rather to the left in the lower abdomen was the pregnant uterus and that the position of its upper border—rather above the level of the umbilicus—at that period of pregnancy was accounted for by the presence of the hard swelling in the pelvis It seemed to me to be quite certain, even at this time that the presence of the hard tumour to the right of the cervix would render delivery at full term of a living child absolutely impossible I was not at this time at all certain whether it was a fibroid of the broad ligament or a fibroid growing from the right side of the cervix out into the broad ligament. The possibility that the tumour might be an ovarian tumour, more or less adherent in the right side of the pelvis, was not overlooked. I advised that, if possible, the patient should be allowed to go to full term and be delivered by Cæsarean section. But I suggested that she should be examined from time to time, so that any alteration in the position or mobility of the pelvic tumour might be recognised On Jan. 24th the patient was carefully examined at a nursing home under anæsthesia and the result of the previous examination was entirely confirmed. By this time most of the symptoms (pain and so on) had practically disappeared and she was fairly comfortable. She went on in much the same way during the succeeding months. I did not see her again until May 6th. On examination on that day the physical signs were very similar except that the patient was now about eight months pregnant and the hard lump in the right side of the pelvis, described at the earlier examination, was decidedly larger, so that the vaginal cervix was even more difficult to reach than it had been in January According to my calculation from the date of the last menstruation it appeared that labour might be expected to commence about June 15th It was arranged that the patient should go into a nursing home about June 3rd and that the operation should be performed about the 10th—that is to say, about five days before full term. These arrangements were exactly adhered to She went into the nursing home on June 3rd I saw her on the 8th and asked my friend Dr W J Gow to see her with me. He was of the same opinion as myself, that delivery by Cæsarean section was the right treatment.

The operation was performed on June 10th at two o'clock. Dr Gow kindly assisted me and Mr H Bellamy Gardner gave the anæsthetic. On making the incision into the uterus it was found that the placenta lay under the line of the incision. The opening into the uterus was completed as quickly as possible and the placenta removed with the hand. A leg of the child was seized and delivery was completed without difficulty The child, a female, was alive and both in size and other respects corresponded to the development usual at full term. In a minute or two she cried vigorously The uterine wound was stitched up with two sets of sutures, deep sutures through the peritoneum and muscular coat, stopping short of the endometrium, and numerous superficial sutures for the peritoneum. The sutures were of silkworm gut. Examination of the pelvic tumour from above seemed to make it clear that the tumour was not a uterine fibroid growing out from the tissues of the uterus but a fibroid imbedded in the right broad ligament. An attempt to sterilise the patient was made by pinching up a loop of each Fallopian tube, tying tightly, and cutting off the loop The abdominal wound was completely closed. The operation lasted three-quarters of an hour and in spite of the placenta being in the line of the uterine incision no very large amount of blood was lost. The pulse was quite good at the end of the operation. The patient made an absolutely uneventful recovery and had very little pain during the two or three days after the operation, so little that she did not wish to have any morphia. She was able to suckle the baby partially The child also did perfectly well The mother and child left the home at the end of the first week in July

CASE 2—A patient, aged 35 years, was brought to see me by Dr T E Foster MacGeagh on June 2nd, 1902. She had been married ten years but had never been pregnant She had been quite well up to about four months previously Menstruation had as a rule occurred regularly every four weeks The quantity lost had been moderate and she had not usually had much pain at the time. Latterly she had had no pain at all at the periods. She had menstruated in February, the last day of the period being Feb. 12th, and since then there had been amenorrhœa. At the time I saw her she complained of a good deal of pain all round the lower abdomen and in the lower part of the back also that her "clothes had become very tight" for her She also complained that she passed urine frequently and she had also felt a little nausea in the morning All these symptoms had arisen within a few weeks of the time when she first came to see me She said that her appetite had been very good She had had no vaginal discharge of any kind. She seemed to have usually led an active life and had been accustomed to ride and cycle up to March, 1902. On examining the abdomen a soft, elastic, somewhat globular swelling was felt rising out of the pelvis and reaching to within about an inch of the umbilicus Although the general outline of the swelling was fairly uniform slight irregularities of its surface were felt in one or two places. A loud uterine souffle was heard over the swelling but no rowth was thickest at the pylorus, and here it measured ne-third of an inch in depth, traced towards the fundus it ecame gradually less and less thick. The pyloric orifice as narrowed barely admitting the tip of the little finger he mucous membrane of the organ was everywhere intact nd presented no signs of ulceration, either recent or old he duodenum was healthy The mesentery of the jejunum nd ileum presented many small nodular thickenings situated etween the two layers of the peritoneum close to the bowel nd spreading in places into and around the wall of the owel and causing a decided thickening of the bowel t these places. The cæcum was thin and a little ilated, the colon was thick walled, but there was no arrowing of the lumen. The thickening of the colon as due to an infiltration of the wall by a pearly omogeneous glistening growth similar in appearance nd in distribution to that affecting the stomach. The rowth was thickest at the attachment of the colon to he meso-colon, and it became thinner as it was traced owards the free surface of the colon. There was no ulceration of the mucous membrane of the intestine The mentum was free from growth and there was no enlargement of the mesenteric or retro-peritoneal glands There were no metastases Each kidney was in an advanced condition of hydro-nephrosis, due to the impaction of calculi in the pelvis The other organs were healthy There was nothing found post mortem to account for the subphrenic abscess drained during life, although the adhesions in the upper part of the abdomen were the probable result of this collection of pus There were no symptoms during life suggesting the presence of renal calculi, in fact these and the resulting hydro-nephrosis were quite unexpectedly found at the necropsy

---

[3] Transactions of the Obstetrical Society of London vol xliii 1901, p 183.

CASE 3.—A man, aged 56 years was admitted into the General Hospital, Birmingham on Sept. 23rd, 1901 complaining of severe abdominal pain of increasing difficulty in passing his motions and of distension of the abdomen. Prior to these symptoms, which were of gradual onset and of about eight months' duration, the patient had had good health. On admission into the hospital he was very emaciated and very weak. The abdomen was greatly distended and an attempt was made to relieve the distension by tapping, but only about 20 ounces of almost clear ascitic fluid were obtained by syphonage and the distension remained evident. No tumour was definitely felt by palpation but per rectum an obstruction encircling and almost occluding the bowel was found. No ulceration of the mucous membrane was felt in the rectum nor any growth projecting into the lumen The condition suggested a fibrous stricture. When the question of more radical treatment was discussed there was hesitation as to whether the patient would be relieved more by a gastro-jejunostomy or by a colotomy So prominent a symptom was epigastric pain immediately after taking food that malignant disease of the stomach could not be dismissed. It was decided, however, to treat the rectal obstruction which was undoubtedly present rather than to attempt to relieve the problematical condition of the stomach. The subsequent necropsy revealed that either operation alone would have been ineffectual. Colotomy was performed on the 28th, the bowel being opened on the same day Ascitic fluid escaped freely at the operation and leaked constantly from the wound until the death of the patient, which occurred three weeks later from gradual exhaustion on Oct 19th.

At the necropsy the body was found to be extremely emaciated. No jaundice, œdema, or external glandular swellings were present. There was a colotomy wound in the left iliac region into which the sigmoid flexure opened. On opening the abdomen about three pints of hæmorrhagic fluid escaped The peritoneum was acutely inflamed and covered with a fibrinous exudation, matting the coils of intestine loosely together and peeling easily off the intensely injected surface beneath. The œsophagus was healthy The stomach was small and contracted and its wall was greatly thickened throughout—the 'leather bottle" stomach The duodenum and jejunum were thin and somewhat dilated. The walls of the ileum were thickened at places. The cæcum was very small and contracted and its walls were greatly thickened, closely resembling the 'leather bottle" stomach in appearance. The colon was throughout its length contracted and thick walled, the hepatic and splenic flexures and the rectum being so much stenosed that they would hardly admit the little finger There was no ulceration of the mucous membrane of any portion of the stomach or intestines. The thickening of the parts mentioned was due to infiltration of the walls of the gut by a homogeneous looking growth starting at the attachment of the gastro-hepatic omentum, mesentery, meso-cæcum, meso-colon, and meso-rectum to the various viscera (the stomach and the small and large intestines), and spreading into the wall of the bowel in the submucous layer In places it entirely encircled the bowel, but everywhere was obviously thicker and more definite at the attached border and gradually shaded off to the opposite free border of the bowel. The gut was not uniformly affected with the growth. Along the small intestine it could be better felt than seen as small nodular thickenings at the attached border of the bowel. In the large intestine the thickenings were in places very conspicuous and gave rise to the stenoses of the hepatic and splenic flexures and of the rectum mentioned above. The great omentum was free from growth. There was no infiltration of the mesenteric or retro-peritoneal glands There were no metastases The other organs were healthy

The accompanying table is a summary of the important features of these cases.

Case	Sex.	Age.	Prominent symptoms.	Diagnosis	Treatment.	Approximate duration	Site of growth.	Metastases.	Ascites	Site of obstruction.
1	F	27	Anæmia, debility abdominal pain.	General peritonitis	Laparotomy	12 months.	Pyloric end of stomach, small intestine (in places) and colon	Gall bladder kidney	Undeterminable.	Ascending colon.
2	M.	33	Epigastric pain vomiting	Gastric ulcer	Gastro-jejunostomy	3	Whole of stomach small intestine (in places) and colon (whole of)	None.	None.	Pylorus.
3	M.	56	Chronic constipation with abdominal pain and distension.	Fibrous stricture of rectum and (?) malignant disease of stomach.	Colotomy	8	Whole of stomach small intestine (in places) cæcum colon and rectum.	None.	Ascites.	Pylorus cæcum hepatic flexure, splenic flexure, and rectum.

In all the cases the microscopical characters of the new growth were identical in the main, only differing in minor details. We found that the growth was a glandular carcinoma arising in the deeper layers of the gastric mucous membrane and undergoing colloid degeneration. Our conclusions were based on the study of sections from the following parts. In Case 1 (1) the stomach wall transverse section taken at the junction of the infiltrated part with the healthy part, at a point about four inches from the pyloric end, (2) the ileum, transverse section taken at the junction of the bowel with the mesentery, including the mesenteric attachment, (3) the colon, transverse section of the free unattached portion of the wall away from the meso-colon, (4) the metastasis in the kidney, and (5) the infiltrated fundus of the gall bladder. In Case 2 (1) the stomach transverse section of the thinnest part of the infiltrated wall, (2) the ileum, transverse section of the entire intestine, and (3) the splenic flexure, transverse section of the entire intestine. In Case 3 (1) the stomach, transverse section of the thinnest part of the infiltrated wall, (2) the cæcum, transverse section of the free surface, and (3) the rectum, transverse section of the free surface.

In all these sections growth of identical nature and a typical 'leather bottle stomach," while in Case 1 only the pyloric half of the stomach was affected in this manner A similar growth to that affecting the stomach also involved the small and large intestines to different extents in the different cases. In the intestines the growth seemed to start at the attached border of the mesentery or its homologues—viz, the meso-cæcum, meso-colon, meso sigmoid, and meso-rectum—and to infiltrate the wall of the bowel for a varying distance towards its free border, in some parts entirely encircling it and in other parts only spreading into the bowel for a short distance from its attached border In places where the growth had infiltrated the entire circumference of the gut it was thickest at the attached border and gradually became thinner towards the free border In Case 1 the parts affected were the pyloric half of the stomach, the small intestine in places, and the entire colon, while the cæcum was free from growth, in Case 2 the entire stomach was infiltrated, the small intestine in places, and the whole of the colon, the cæcum again being free, while in Case 3 the entire stomach, the small intestine in places, the cæcum, the colon, and the rectum were infiltrated with growth To the colon in all the cases, and to the cæcum and rectum in Case 3 the terms "leather bottle" colon, cæcum, and rectum respectively, might be fittingly applied. In all the cases the growth had spread for a short distance in between the two layers of the mesentery and the meso-colon, and in Case 3 the meso cæcum and the gastro hepatic omentum were similarly affected In Cases 1 and 2 the cæcum and meso-cæcum were unaffected We are not sure of the condition of the gastro hepatic omentum in Cases 1 and 2, as no note was made of these parts at the time of the post-mortem examination In all the cases the great omentum and the mesenteric and retro peritoneal glands were free from growth. The fundus of the gall bladder in Case 1 was infiltrated with carcinomatous growth to the thickness of one eighth of an inch, and there was a small metastatic deposit in one of the kidneys in this case, but with these exceptions there were no metastatic growths in any one of the three cases In all the cases there was in no part of the stomach or intestines any sign of ulceration of the mucous membrane and until microscopic sections were made it was not clear where the growth had originated. The result of this widely diffused malignant disease was to cause stenosis at one or other part of the alimentary tract and sometimes at more than one part in the same case. Thus, the patient in Case 1 died from perforation of the cæcum behind a stenosis in the ascending colon, in Case 2 the patient had gastro-jejunostomy performed for pyloric obstruction, while in Case 3 there was some hesitation between performing a gastro jejunostomy for pyloric obstruction or an inguinal colotomy for rectal obstruction In this case the colotomy was finally decided upon, but the necropsy showed that a gastro-jejunostomy was just as much indicated. Case 1 was that of a female, Cases 2 and 3 were those of males The ages were 27 years, 38 years, and 56 years respectively Ascites was present in Case 3 but absent in Case 2, while the presence of the septic peritonitis in Case 1 made this condition uncertain.

The following is a brief record of the clinical aspect of each case with details of the post-mortem examinations —

CASE 1 —A woman aged 27 years, was admitted into the General Hospital, Birmingham, on June 8th 1901, with general septic peritonitis. Her previous health had been good until 12 months before her admission, and during this time she had suffered from anæmia and debility and indefinite abdominal pain of an intermittent colic like nature. A week before her admission symptoms of intestinal obstruction supervened and she was received into the hospital with signs of general peritonitis She died two hours after her admission during the administration of an anæsthetic, from asphyxia arising from regurgitation of stomach contents into the larynx.

At the necropsy the body was found to be thin with no external glandular enlargements The abdomen was much distended and it contained free gas and about three pints of turbid purulent fluid mixed with fæcal matter There was a general acute septic peritonitis, the entire peritoneum being covered by a thick fibrinous exudation loosely gluing the coils of intestine together The peritonitis was due to the perforation of a stercoral ulcer situated in the cæcum. The cæcum was dilated and thinned owing to its lying above an obstruction in the ascending colon. The œsophagus was healthy The stomach was small and was much thickened at the pyloric end the fundus and cardiac end being of natural thickness The thickening was due to an infiltrating growth of the wall of the stomach starting at the pylorus, where it was one third of an inch in thickness, and spreading for about four inches into the main portion of the stomach, gradually thinning away into the normal stomach wall. There was no stenosis of the pylorus. The mucous membrane and the serous coat of the stomach were quite intact and were not apparently affected by the growth. The duodenum was free from growth but the jejunum, ileum, and colon showed the presence of a similar growth to that in the stomach wall. In the small intestine the growth was present only at certain places along the mesenteric border of the bowel and spread only for a short distance into the wall of the bowel, but the colon was affected throughout its length and here, too, the entire circumference of the bowel was infiltrated Everywhere the mucous membrane of the intestine was intact and showed no ulceration. The lumen of the small intestine was normal but that of the colon was much encroached upon in places by the infiltrating growth The greatest narrowing occurred in the ascending colon and was so marked that the cæcum was much thinned and dilated and contained in its walls a perforated stercoral ulcer The great omentum was free from growth There were no enlarged mesenteric or retro-peritoneal glands The growth, however penetrated for a short distance between the two layers of the mesentery and meso-colon. The liver weighed 56 ounces and was fatty The gall bladder was contracted, thick walled, and empty It was the seat of a similar infiltration to that in the stomach and intestines which had started at the fundus and terminated abruptly at the beginning of the cystic duct. The spleen was soft and small. The kidneys together weighed 10 ounces and one of them contained in the cortex a small ill defined pale patch which on microscopical examination proved to be a metastatic deposit of the new growth The suprarenals were healthy, as were also the bladder and urethra, the uterus, and the adnexa. There were no metastases other than the infiltration of the fundus of the gall bladder and the growth in one kidney

CASE 2.—A male, aged 38 years, was admitted into the General Hospital, Birmingham, on Oct. 3rd, 1901, complaining of epigastric pain of about ten weeks' duration and of vomiting after meals during the past month. His history prior to May, 1900, was not obtainable At that date, however, he had an attack of severe pain in the right side of the abdomen and a right subphrenic abscess was found and was drained by an abdominal incision The cause of the abscess was not ascertainable at the time of the operation or even later at the necropsy He was free from pain after this operation till ten weeks before his admission, when a recurrence of the gastric symptoms appeared He had severe epigastric pain, which was worse after meals and occasional vomiting The pain used to come on periodically in attacks of great severity, lasting for several hours and leaving the patient very exhausted On admission into the hospital he was very emaciated and his general condition was one of marked asthenia The pain was constant, he vomited frequently almost immediately after taking food and consequently was only able to take very small quantities of liquid food at a time. The bowels were opened with difficulty—only by enemata. On Oct 7th, 1901 anterior gastro-jejunostomy was performed—a Murphy's button being used. He sank and died on the 10th

At the necropsy the body was found to be very emaciated, but with no œdema, jaundice, or external glandular swellings There was an old laparotomy scar through the right rectus abdominis close to the costal margin—the incision through which the subphrenic abscess had been drained in May, 1900—and there was a recent wound in the middle line through which the gastro-jejunostomy had been performed On opening the abdomen the upper part of the peritoneal cavity was found to be obliterated by an entangled mass of firm fibrous adhesions and the jejunum was seen to be anastomosed to the anterior wall of the stomach by a Murphy's button. The union was good, the button was *in situ*, and there were no signs of recent peritonitis. The vermiform appendix was healthy but very long and passed up over the right kidney imbedded in firm adhesions and its tip lay almost touching the fundus of the gall bladder The œsophagus was healthy The stomach was very small and contracted and its walls were much thickened—the "leather bottle" stomach. The thickening was seen to be due to a submucous infiltrating growth of a pearly homogeneous glistening appearance The condition of extreme hæmorrhage nearly always means endometrial invasion and is generally associated with a submucous or polypoid tumour Nearly all the patients suffered at times from some degree of pressure effect, especially on the bladder Two had suffered from retention of urine and accompanying cystitis for several months, and three from backward ascending trouble, leading to pyelitis and kidney disease. In the majority of patients the disabling effect is produced by a combination of repeatedly recurring moderate loss, with constant discomfort, pain, and pressure, and thus the nervous resistance of these patients is worn down by the vicious circle No doubt the social condition of the patient is a very important factor in deciding as to the necessity or otherwise for operation. This point will be alluded to again in the concluding remarks. The case of a poor woman who has to earn her living and to support her family is on a different level from that of a lady surrounded by luxury, for while in the first case it is essential to restore the patient to moderate health in order to avoid starvation or the workhouse, in the other case the favourable surroundings, while removing the necessity for operation on these grounds, do so by enabling the patient to struggle with the disease instead of being overwhelmed by it. Rest and luxury never cure fibroids. What they can do is to enable the patient to live the life of an invalid, a privilege denied to the poor, and in the case of the rich patient, if it is wished to enter again on the enjoyment of the work and duty of life, the necessity for operation is as important a factor in the one case as in the other

3 The condition of the appendages in cases of fibroid disease is an interesting point. In 18 cases one or both ovaries were cystic—that is, they contained cysts varying in size from that of a filbert to that of a hen's egg and in some there were signs of peri oöphoritis. In one case there was hæmato-salpinx, in two cases double pyo-salpinx, and in five cases hydro-salpinx. No doubt the association of tubal disease with fibroid tumour is an accidental one to a certain extent and depends on previous gonorrhœal infection and also on puerperal infection following the miscarriages to which these patients are especially subject. In a series of cases drawn from hospital patients such conditions will no doubt be especially frequent. I am, however, inclined to think that the oöphoritis and cystic changes in the ovaries are intimately associated with the tumour formation in the uterus. It is, at any rate, true that those cases have presented the worst symptoms, especially as regards pain, where the appendages have been affected. This would no doubt be expected and the difficulties of the operation are, of course, considerably increased by previous pelvic inflammation. In three of the cases the uterus contained at the time of operation an ovum from six weeks to three months old This condition was suspected before operation and was not considered a contra indication to its performance. In one case caseating tuberculous foci were present in the Fallopian tubes and tuberculous disease was proved to be present in the endometrium by microscopic examination As to the size of the tumour this varied from the enormous tumour occupying the whole abdomen and interfering with respiration, to the small intramural multi-nodular or submucous tumour which, though inconsiderable in size, often gives rise to urgent symptoms.

4 Degeneration in fibroid tumours is, I think, more frequent than is generally supposed In most of the cases of large single tumours degenerative changes were noticed in the centre, cystic changes, too, were frequently found. and this is well shown in the case of a fibroid in Douglas's pouch in which the greater portion of the swelling has been converted into a cyst containing clear yellow fluid. If the tumour be single this condition might give rise to insuperable difficulty in diagnosis, in this case the swelling was only one of several outgrowths The occurrence of degeneration cystic or otherwise, in a tumour does not seem in any way to lessen the hæmorrhage or other symptoms referable to the fibroid, nor is its presence inconsistent with a further growth of the tumour at its periphery or with the growth of other tumours

5. In two cases in addition to moderate-sized tumours, an invasion of the uterine wall by very numerous small fibroids was noted, little whorls of involuntary muscular tissue, showing all stages between this and the recognisable larger tumours. Bland Sutton and others have reported cases of this character and have drawn attention to this condition. In one of the worst cases of hæmorrhage in this series (No 2556), which previous curetting had failed to relieve, the condition found was one of marked hypertrophy of the uterine walls, which on microscopic examination was found to be due to this infiltration by microscopic fibroids, the benign character of the growth was, I think, shown by the complete recovery and absence of any recurrence after operation

6. The question of the association of fibroid disease with cancer of the uterus should be considered separately from that of the association of fibroid disease with cancer of other parts of the body In one case a large uterine fibroid was associated with a pre-existing scirrhus of the breast with glandular recurrence after removal. The effect of removal of the ovaries was very marked on the uterine hæmorrhage and the size of the fibroid, but had little effect on the course of the malignant disease, from which the patient died later One case (No 1910) of enormous fibroid was also associated with cancer of the sigmoid flexure and this was only discovered after the removal of the uterine tumour which filled the abdomen. The patient underwent inguinal colotomy for the relief of the obstruction due to the cancer of the colon and eventually died from the disease some months later The question of the association of fibroids with cancer of the uterus is an important one and can be best considered in relation to the subject of the natural history of fibroids in patients who have not had the tumour or the uterus removed by operation In recalling the histories of such cases as have come under observation during the last few years I can recall two, one of a married woman, a multipara, and one of a single patient, in which operation was declined or was not thought desirable, in which long years of invalid life were passed through owing to pressure and hæmorrhage before the climacteric, and in which after that period the symptoms of cancer of the uterus appeared and the disease ultimately killed the patients. Out of 16 cases of vaginal hysterectomy for cancer, &c., in one case the disease was associated with a moderate-sized fibroid

7 As to the nature of the operation there is no doubt that surgeons are now largely benefiting by the tentative and anxious labours, trials, and failures of the early operators, Keith, Spencer Wells, and Lawson Tait. In fact, I believe that up to the last an abdominal hysterectomy was always undertaken by Lawson Tait with anxiety and some amount of misgiving, and Keith was always anxious as to the result. It was only when the technical knowledge of pelvic operations gained by British and foreign operators was based on the bedrock principles of aseptic surgery, that the cloud of anxiety was fully lifted and that it became possible to undertake a complicated case of abdominal hysterectomy with as great a sense of mastery and assurance as has been the case for many years in ovariotomy I well recollect the sense of depression with which I closed the abdomen without feeling justified in attempting at that time to remove a very large uterine fibroid with pelvic extensions in 1886, and also the humbling effect of the lesson I learnt from an equally serious case of the same kind at about the same time, in which after advising the patient that operation involved too great a risk, and that rest, palliative remedies, and invalid life were the only course, she returned from Birmingham shortly afterwards with the uterus and tumour removed and health restored. Since that date the confidence, knowledge, and skill necessary to deal successfully with these cases have fortunately spread from the chief surgical centres all over the country

In the above series, in the first seven cases of abdominal hysterectomy up to 1895 Kœberle's serre nœud was used, except in one case in which a stout silk ligature was employed, and the stump was treated extra peritoneally on the same lines This operation, though fairly safe as regards life involved much pain from dragging and a retarded and uncomfortable convalescence. In 1896 the operation of panhysterectomy was performed in one case and from 1896 onwards to the present time in all the cases the uterus has been removed above the level of the internal os after ligaturing off the broad ligaments the formation of peritoneal trans-pelvic flaps and also flaps composed of the tissues of the divided cervix, and the enucleation of any outlying masses of tumour Accurate suturing of these two lines, the uterine and peritoneal, leaves the pelvis in practically a sound state and no injury is done to the pelvic floor In some of the cases special difficulty arose Thus, in No 2726, the subject of two previous operations, distribution was found, but the colloid degeneration was variously advanced in the different cases and of varying degree in the different parts of the same case. In all the distribution of the growth was identical. It formed a very thick continuous layer occupying the submucosa and another less thick but still continuous layer occupying the subserosa, and these two layers of growth were united to one another by strands of growth of varying thickness, splitting up the muscular layers of the stomach and intestines into bundles of muscular fibres of varying size. In the sections of the small and large intestines of these cases the muscularis mucosæ and the mucous membrane beyond were for the most part intact, occasionally, however, a mass of glandular carcinoma was found occupying the deeper parts of the mucous membrane and penetrating through the muscularis mucosæ to become continuous with the main mass of growth in the submucosa In the stomach sections, however, while the growth had the above general distribution it could be seen to arise in the deeper layers of the mucous membrane as a typical glandular carcinoma, to penetrate the muscularis mucosæ and to become continuous with the main mass of growth in the submucosa, with which again the subserous layer of growth was joined by strands of growth splitting up the muscular coat.

As we have said, the amount of colloid degeneration varied in the different cases and in the different parts of the same case. In any particular section the degeneration was seen to become more advanced as the growth was traced outwards from the mucous membrane to the serous coat, so that in every case the growth occupying the subserosa was more degenerated than the layer of growth in the submucosa of the same part. Many of the sections showed the different stages of colloid degeneration in a very beautiful manner Throughout the sections the cells of the growth stained but faintly They showed great inequality in size and there was a general tendency to increase in size as one passed from the mucosa to the serosa. With this increase in size there was a marked tendency to vacuolation and granularity of the protoplasm with displacement and distortion of the nucleus till in the serosa large spaces filled with colloid material and containing only the débris of pre-existing cells were met with. This degenerative change which we believe is of a colloid nature, was only appreciable microscopically There was nothing in the macroscopical appearance of the stomach or intestines to suggest such a change. Everywhere the infiltrated part of the stomach and intestines was of leathery hardness and we anticipated a fibrous infiltration of the parts rather than the invasion by carcinomatous growth which we found. In fact, when the necropsies were first made we thought we had the condition described in Osler's "Medicine" ("proliferative peritonitis") in which a thickening of the peritoneum is found associated with cirrhosis of the cæcum and ascending colon or of the stomach Some of the sections in which the degeneration was so advanced that practically no definite epithelial cell elements remained—the tissue appearing as a fibrous meshwork inclosing apparently empty interspaces—helped to bear out the opinion formed on an examination by the naked eye only, that the entire process was a diffuse fibrosis. A consideration of sections, however, from different parts and the evidence they afforded of different stages of the same degenerative process have led us to our final conclusion that these were cases, not of a diffuse fibrosis, but of a diffuse carcinomatosis undergoing colloid degeneration This degeneration was most marked in Case 2 and least marked in Case 1. In Case 2 the degeneration was more advanced in the splenic flexure than in the ileum and more advanced in the ileum than in the stomach In Case 3 the degeneration had an exactly opposite distribution, being more advanced in the stomach than in the cæcum, and more advanced in the cæcum than in the rectum, while in Case 1 in the stomach the degeneration was only present in the subserous layer of growth while in the ileum and colon the submucosa as well as the subserosa showed marked degeneration

We have referred at some length to the presence of the degeneration in these growths because it so masks the true (carcinomatous) nature of the growth in many of the sections that when we showed specimens of these cases at the meeting of the Pathological Society of London held on April 29th, 1902 [3] we were altogether in doubt as to their exact nature and we suggested that they might be endotheliomata. A more careful study of the sections, however, has brought us now to the conclusion that they are carcinoma arising in the deeper layers of the gastric and intestinal mucous membranes undergoing colloid degeneration. We do not seem to have been alone in describing these specimens when they were shown last April as endotheliomata, as a statement in the *Centralblatt für Gynäkologie* shows On page 1109 in No 42 (Oct. 18th, 1902) we read the following "Many so-called endotheliomata of the intestines are only metastases of, for example, scirrhus of the stomach."

We have not been able to find any account of such widespread carcinomatous infiltration of the stomach, the small and the large intestine, in the literature of malignant disease of the intestinal tract and so we have reported these cases in some detail We wish to thank the staff of the General Hospital for permission to publish these cases.

Birmingham

ON THE RESULTS IN 50 CASES OF ABDOMINAL HYSTERECTOMY FOR FIBROID DISEASE OF THE UTERUS

WITH REMARKS ON THE AFTER HISTORY OF THE PATIE AND ON THE ARTIFICIAL MENOPAUSE

By C J BOND, F R C S Eng,
HONORARY SURGEON TO THE LEICESTER INFIRMARY

THERE is, I think, no doubt that medical opinion is s in a somewhat transitional and uncertain state as regards t wisest and best treatment for fibroid disease of the uter We need only recall recent debates at various societies order to illustrate the wide gulf which separates the views the conservative school, on the one hand, from those of t operative school on the other It is in order to add a sm portion to the sum total of positive knowledge on this i portant subject that I venture to bring forward the essenti features in 50 cases of operation for fibroid disease whi have been under my care during the last few years. I ha been especially anxious to ascertain by personal inves gation the real condition of these patients some yea after operation, to find out what sort of health they real enjoy and to what extent they are able to fulfil the duties citizenship and to take their share in the work or play of li

The investigation of the after histories of these cas is not an easy matter and I wish to give one word of cauti against hastily accepting the unverified statement of patient without opportunity for personal interview and cros examination. Many female patients who have undergone operation which, in their own eyes and that of their friend is of a heroic character are apt to give a corresponding coloured account of their later condition and they eith magnify or minimise their sufferings, or their cure, accordin to the sanguine or melancholic bent of their minds I those cases in which I have been unable personally to se the patients I have obtained valuable information from th medical men in attendance. The cases have been arrange in series in a table under the following headings Hospit or private number, age, date, married or single, an number of children, character of menstruation, presence pain, and pressure symptoms, length of disabling illnes the nature of the tumour, the condition of the appendage the nature of the operation, the primary result, the resul at the present time, together with remarks

The following lessons are to be learnt from a study o this limited series of cases of sufferers from fibroid diseas sufficiently disabling to necessitate a serious operation

1. The first point is the unfortunate history of prevailin sterility and of frequent and repeated miscarriages. In othe cases the disease may be regarded as an impediment t marriage Thus, out of 50 patients 20 were unmarried an out of the remaining 30 married women there were 11 miscarriages and only 33 children

2 The disabling effect of the disease on the workin capacity and enjoyment of life of the sufferers depends no alone, or indeed chiefly in most cases, on the profusenes of the menstruation, but on the pain and pressure effects o the pelvic tumour Of course, in cases of violent flooding this alone renders the patient a complete invalid, and this

REMARKS —[1] Symptoms of menopause were slight and normal. [2] Both the ovaries and the tubes were removed hæmosalpinx. [3] Moderate menopause both ovaries were removed. [4] Both ovaries were removed. [5] Left ovary was cystic, of the size of a cocoanut the right ovary was gangrenous [6] Convalescence was delayed by prolapse of the bowel through abdominal wound. [7] Works as a nurse. [8] Operation of partial myomectomy three years previously [9] Hæmorrhage the peritoneal flaps were stitched to abdominal incision cavity tamponnaded [10] Uterus contained a two months ovum. [11] Colotomy for cancer of the colon [12] Miscarriage occurred two months before the operation [13] Normal menopause curetted three months previously [14] Patient had peritonitis at the time of the operation also pyelitis from pressure on ureter [15] No neurosis [16] Moderate menopause. [17] Slight neurosis. [18] Moderate menopause lasting 12 months [19] Patient had peritonitis profuse sweatings during the menopause. [20] Both ovaries were left the patient menstruates regularly [21] Hæmorrhage during the operation [22] Died from pyelitis existing before the operation nephrectomy [23] Patient had had retention a month before the operation tuberculosis of peritoneum, tubes and endometrium. [24] Patient had had two previous abdominal sections enterectomy [25] Slight neurosis. [26] Small hernia [27] Heart disease no pelvic complication. [28] Recovery of the patient was delayed by pyelitis [29] Left ovary was removed. [30] Normal menopause the left ovary was removed. [31] Albuminuria before the operation.

enterectomy was necessary owing to dense adhesions In one case (No. 1852), owing to persistent hæmorrhage uncontrollable by forcipressure or ligature, I was obliged to bring up the peritoneal flaps to the abdominal incision and to tamponade the bleeding cavity thus shut off from the peritoneum.

8 One of the most important points that comes out in the consideration of these cases is, I think, the establishment of the fact that the uterus may be readily and safely amputated at almost any level. It is not necessary always to remove the organ just above the internal os, the seat of election, provided that removal at a higher level efficiently removes all sources of present and future trouble In several cases the uterus has been removed at a considerably higher level and in one case (No. 2329) at a point sufficiently high up in the uterine cavity to allow of regular and free menstrual periods for some years afterwards. Moreover, in three cases of Porro's operation the procedure adopted was in reality a modification of Porro's method. The first case was treated by the serre-nœud in the usual position without separate ligature of the broad ligaments, the obstruction to labour at the full time being due to a dwarf pelvis. In the second case the obstruction was caused by large double adherent ovarian cysts behind the uterus, malignant in origin, and the uterus was amputated four inches above the level of the internal os, after ligature of the broad ligaments, the uterine flaps being involuted and sutured. In the third case, owing to the implication of the lower segment of the uterine body in the malignant mass of rectal cancer, the pregnant uterus was amputated about halfway down and just below the level of the insertion of the placenta. The somewhat voluminous uterine flaps were

the ovarian element in connexion, of course, with the nervous system, and to regard the uterine influence as of less importance in its effect on the nervous system, although the local sanguineous discharge is the more striking and obvious phenomenon. In the natural climacteric both factors undergo orderly and simultaneous involution, while the irregular phenomena of the artificial menopause may be due to the absence of coördination and simultaneity in this process of involution.

12 As regards the sexual phenomena shown by these three groups of cases generalisation is difficult As far as I have been able to ascertain by careful inquiry the sexual appetite persists, or is only slightly impaired, in those cases in which the uterus has been removed above the cervix and the ovaries left. In cases where the ovaries have been removed with the uterus I think there is no doubt that the sexual appetite is lost, and in cases of removal of the ovaries alone I think, in spite of the assertions of some writers to the contrary, that it is certainly diminished or lost.

CONCLUSIONS

The decision as to operation in cases of fibroid disease of the uterus must depend on the danger to life and the amount of disablement, ill health, and suffering which are caused by the disease. The social condition of the patient is also a factor to be considered, and since a comfortable *invalid life is incompatible with poor circumstances* we are not justified in withholding from poor patients the restoration to working capacity which the operation of hysterectomy, if successful, confers In patients in a better social condition the very serious moral, mental, and physical effects of long continued invalid life are not sufficiently appreciated by medical men. In nearly all cases where the disease causes disablement or where the hæmorrhage, pain, and pressure are sufficiently severe to threaten ultimate serious damage to the general health, to the nervous system, or to the pelvic viscera, in these cases the possibility of cure by operation should be laid before the patient and if the conditions are favourable the operation should be advised.

The operation of abdominal cervical hysterectomy as now carried out has a lower mortality in capable hands than is sometimes represented (4 per cent) and is comparable with that of ovariotomy The uterus can be safely amputated at any level, and the absence of recurrence of fibroid disease in the stump or cervical portion of the uterus—in any case in the present series—is an argument in favour of cervical amputation as against panhysterectomy In the former case also, the pelvic floor is left intact.

Myomectomy, the enucleation of one or more fibroid tumours with the preservation of the uterus as a whole, is a conservative operation of much value and should be practised in the case of *single and accessible tumours*

In all cases where possible, one or both ovaries should be left in the operation of hysterectomy for fibroid disease. The beneficial effect of this procedure is shown in the more complete convalescence and the modified character of the artificial menopause.

Leicester

A NEW "FILM" DRESSING FOR WOUNDS

BY PEYTON T B BEALE, F R C S ENG,
SURGEON TO OUT-PATIENTS KING'S COLLEGE HOSPITAL SURGEON TO IN-PATIENTS GREAT NORTHERN CENTRAL HOSPITAL.

ALTHOUGH "cyanide gauze,' now in general use for dressing wounds, has been found to be very satisfactory, I think that it can hardly be considered a perfect dressing It is usually employed in the following manner A piece of cyanide gauze consisting of about ten layers and moistened with some antiseptic lotion, is laid on the wound, care being taken that it overlaps the wound at least five inches in each direction. Over this some layers of dry gauze are applied and this is covered with several sheets of sterilised cotton wool, usually a wool impregnated with an antiseptic such as salicylic acid or boric acid. This wool again overlaps the gauze several inches in each direction and the whole is kept in position by bandages more or less firmly applied A good deal depends upon the firmness with which the bandage is applied, for it prevents the whole dressing from slipping Such a dressing must, from its bulk and heat, be uncomfortable to the patient, at any rate in most situations, moreover, it must be removed in order to see how the wound and the parts around it are progressing The removal must be accomplished under conditions which are very familiar and which are often termed "strict antiseptic precautions."

The fact that we employ so many thicknesses of gauze and wool seems to me to imply that we are afraid of septic organisms gaining access to the wound from the air, and the fact that we apply a dressing over so large an area, and with considerable firmness, that we fear the access of these organisms from the skin around the wound. I am told that the late Sir George M Humphry of Addenbrooke's Hospital, Cambridge, in pre antiseptic and aseptic days found that his amputation stumps healed best when they were exposed freely to air and light and that he used to have the stump projecting beyond the bedclothes in front of a window, and that under these conditions the wound very rarely suppurated. I believe that if we were to practise aseptic surgery and to treat our wounds at the present day in this manner we should obtain even better results, but unfortunately it would be impossible in any city to obtain pure air and it would in other ways be quite impracticable in our hospitals The next best thing would be to seal up our wounds hermetically with some material which is aseptic and which is gas and fluid proof and upon which we can apply as much pressure as may be necessary If such a substance were transparent I think it would be an ideal dressing

During the last 12 months, through the kindness of Mr Walter Reid, managing director of the Velvril Company, I have been using thin films of a substance known as "Velvril' as a wound dressing and I have so far applied it to over 100 wounds with very excellent results. Velvril is one of the many cellulose derivatives and can be produced cheaply in the form of films of any thickness in several ways. When in the form of a film it has the following characteristics It is transparent, but slightly yellow in colour, it is absolutely impermeable to all ordinary gases and fluids, it is tough and elastic and very durable, it can be easily sterilised by any of the ordinary methods, and it can be immersed in boiling water for a long time without undergoing any permanent change. It can also be easily dissolved in acetone and its solution in that fluid is quite unirritating even when in contact with a freshly made wound. The solution is, from its method of manufacture, absolutely sterile. After making various experiments I find the following method of using the film and solution gives uniformly perfect results. It is, of course, assumed that the usual precautions relating to the sterilisation of the skin of the patient and that of the operator's hands and of all instruments, towels or cloths sponges, and swabs, have been fully adopted

When the operation has been completed a piece of the sterilised velvril film is cut large enough to cover the wound and the skin round it for at least one inch in each direction. If a drain is to be used a sufficient opening is cut in the film to receive the tube or plug The wound must be as dry as possible and if ordinary methods do not suffice to check capillary oozing, washing out the wound with 50 per cent. of alcohol and sterile water will be found very efficacious The piece of film should be placed upon a boiled cloth or towel until required for use. Should the exposed surface of the film become accidentally moistened it should be gently wiped with a piece of dry sterile wool moistened with acetone. When the wound has been sutured it and the skin all round are washed freely with acetone, using dry wool as before. The wound and the skin round it for at least one inch in each direction are then painted with velvril solution applied freely, and the film is then placed upon it, the exposed surface next the solution. Upon this is placed a pad of sterile dry wool[1] and the whole is bandaged firmly, making as much pressure as may be considered necessary It is advisable to apply considerable pressure for the first 12 hours or so The preliminary washing of the skin and wound with acetone is necessary in order to remove all trace of water, the solution and the film then stick so firmly that it is absolutely impossible for any gas or fluid to gain access to the wound. If the film is left to itself it will peel off in from 10 to 12 days bringing the superficial layer of dead epidermal cells with it. A few fibres of the wool adhere to the film, so that if the wound is to be examined turned in and sutured and the peritoneum was sewn over, a more secure condition being thus left than would have been possible after Cæsarean section.

---

[1] Salicylic wool makes a much better pad than absorbent wool It is firmer and more elastic.

9 *The primary result*—In this series of 50 cases two patients died from the immediate effects of the operation In one case the patient was in a very exhausted state from the long illness She had a double pyosalpinx and died from a subacute peritonitis, no doubt due to infection of the pelvic peritoneum from escape of pus at the time of operation In the second case (No 1388) an enormous fibroid and two large ovarian cysts were present, one of which was gangrenous from a twisted pedicle. Peritonitis was also the cause of death. In one case (No 2827) the patient died suddenly from syncope after an uneventful convalescence on the fourteenth day The necropsy showed nothing wrong with the pelvic area. In one case (No 1416) recovery was complicated by a giving way of the abdominal incision some days after the operation during a violent cough, and a coil of bowel escaped, this was, however, returned after due cleansing and the wound was reclosed without any marked effect on the patient Thus, in the series of 50 cases of abdominal hysterectomy for fibroids two deaths only occurred and primary recovery occurred in 48 cases—that is, if we exclude the death after convalescence on the fourteenth day, and if we take the last 43 cases all treated intraperitoneally there has been no death

10 With regard to the permanent or later result of such an operation as hysterectomy, the state of health of the patient at the present time is regarded as the measure of the success of the surgical operation The result can only be regarded as perfect from this point of view when the patient is free from any discomfort or disability, as far, at least, as the operation is concerned In some cases though relieved by the operation of all further hæmorrhage and suffering, yet the preceding years of illness have left their impress on the patient's health in the shape of a diminished nerve elasticity and a lower level of health. In some cases, too, where both ovaries have been removed the complicating effect of this procedure is also shown in the artificial menopause. In 38 cases the patients are now in good health, and able to get about, in some cases to carry on their domestic duties and in others to ride or drive or bicycle One patient (No 2416) died six months after the operation from heart disease and dropsy Another (No 2651) died six months later after nephrotomy for the relief of a pyonephrosis, the result of pre existing pressure and urethral infection A third, though relieved of pain, pressure, and hæmorrhage, is still confined to bed with the effects of venous thrombosis in the thigh and leg Another patient (No 1910) died from the cancer of the colon present at the time of operation. In four cases I have been unable to trace the patient

11. In considering the subject of the artificial menopause I wish to draw attention to one or two points which I think have been overlooked by gynæcologists. From the facts and conclusions drawn from a careful study of these cases and from the observation of other cases we are justified I think, in separating the different factors, the uterine and ovarian elements, which combine together to regulate the menstrual function Thus, I would speak of the uterine climacteric and the ovarian climacteric. No doubt in the ordinary course of events in most females aged from 45 to 50 years these factors, the uterine and ovarian, undergo involution pretty much together The nervous mechanism which is concerned in the regulation of the function gradually also follows suit and accommodates itself to the altered state of affairs in the peripheral end organs, and gradually, though not without difficulty (as shown by the flushings and other vaso-motor disturbances), settles down to the new *régime* Now in the above cases of artificial menopause or early climacteric the result of the operation, we can separate those cases in which the uterus has been removed and the ovaries or ovary left from those in which both ovaries have been removed as well as the uterus and compare these with cases of oophorectomy for fibroids and other conditions in which the uterus has not been removed. The interpretation of the results in a small number of cases is not without difficulty and further careful observation is needed

I find that there are seven cases of abdominal hysterectomy in which one or both ovaries were left and in which I have been able personally to interview the patient as to her subsequent condition—viz No 2294 No 2329, No 2807, No 2523, No 3027, No. 3051, and No 3096 To these may be added two cases of vaginal hysterectomy in which one ovary was left, and two cases of vaginal hysterectomy for cancer in young women in which there was no recurrence Most cases of vaginal hysterectomy for cancer are useless from this point of view, as many are performed at or just about the menopause, and in many local recurrence unfortunately is too common In these cases I have been strongly impressed with the greater rapidity of convalescence, the smaller disturbance of nerve balance and the far greater measure of good health and enjoyment reached by those patients in whom the uterus has been removed and the ovaries left, as compared with the other class in which the ovaries have been removed with the uterus In both, of course, the monthly uterine discharge ceases, but in the first class the climacteric is primarily uterine and not ovarian, while in the second class the climacteric is primarily both uterine and ovarian In fact, where one of the end organs, the ovary remains, certain periodically recurring nervous phenomena, such as headache, weight in the back, &c., seem to point to the fact that the ovary is still keeping up some of the periodic events which go to form part of the cycle of the menstrual phenomenon, the patient goes through a part only of the menopause at first—the part due to the removal of the uterine factor—and only gradually and later through the other portion when subsequent changes and involution occur in the ovaries Further observation is urgently wanted on this question as to the persistence of ovulation after the removal of the uterus. The flushings and irregular vaso-motor phenomena are also less pronounced in those cases where the ovaries remain—in fact, I think, are generally absent. These flushings and other nerve phenomena are, of course, the constant accompaniment of the natural menopause, in which I presume the uterine and ovarian elements undergo involution together and here they are not periodic—the ovarian influence, which I believe to regulate the periodicity of the nervous and other phenomena, having been removed, the vaso motor disturbances are to be regarded as the irregular explosions of a nerve centre or reflex chain which has been deprived of its escapement mechanism and is unregulated by any end organ influence

Now if we compare these cases of hysterectomy where an ovary is left with the remaining majority in which the ovaries have been removed along with the uterus, we find that the latter approximate more nearly, in the phenomena of their convalescence and artificial menopause, to patients in whom the ovaries alone have been removed for fibroids or other causes—in fact, to cases of oöphorectomy, provided, of course that the removal has been complete and that menstruation has been entirely stopped Flushings, irregular nerve storms, and explosions, and radiating effects on the higher centres, psychic and hysterical phenomena, are more common. Local pelvic discomfort is also more marked, whereas in the oöphorectomy series these phenomena reach their climax. With the removal of the chief regulating end organ as regards periodicity—viz., the ovary—the persistence of the other end organ the uterus, although in a partly functionless state, seems only to delay the final settling down of the nervous mechanism the function of which has now been lost and to keep up a local pelvic sense of discomfort.

It is at present premature to discuss at any length the manner in which these different end organs produce these results. With regard to the uterus I showed[1] that in the rabbit, the guinea pig and the sheep one function of the endometrium and mucous membrane lining the Fallopian tubes is to secrete a saline fluid which in the absence of external escape is probably re-absorbed and is in reality an internal secretion, and further that during pregnancy this secretion is in abeyance This secretion may have an important local and general influence. An internal secretion in the case of the ovary has been presupposed by many writers but has not at present been isolated or its effects defined

Although further facts and observations are urgently needed we are tentatively able to regard the menstrual phenomenon as made up of three factors, the uterine and ovarian elements or end organs and the nerve factor Further, the results of operative removal of one or both of these end organs have enabled us to dissociate their combined influence on the phenomenon of the climacteric or artificial menopause so produced We are thus led to recognise a uterine climacteric and an ovarian climacteric, and to attribute the function of regulation of periodicity to trace of an inferior turbinate body left, and in which the atrophied muco-periosteum is stretched tightly over the outer nasal wall, and when one attempts to inject wax into this attenuated fragment of inferior turbinate the needle either passes completely through or, after a few minims have been injected, the mucous membrane gives way and no lodgment of wax is obtained. To say, however, that it is impossible to inject such noses is, I believe, rather overstating the case, for patience and perseverance will eventually enable the surgeon to inject a few minims either into some part of the turbinate itself or under the tissues adjacent, from which the process of lifting the periosteum from the bone, once started, may gradually be continued into the turbinate itself although the results obtained in these cases are only very moderately satisfactory

---

[1] Journal of Physiology, February 1898

The wax used for this purpose should be white paraffin wax melted at 105° F This is better than wax melting at a higher temperature mixed with vaseline to reduce the melting point, as has been advocated for similar work, as the vaseline seems to be more easily absorbable by the tissues than the paraffin. Non absorption is essential if it can be obtained. The syringe required should hold about 30 minims and the most serviceable length of needle is about two and a half inches. My larger needle is about one sixteenth of an inch in external diameter and the smaller one of the size of a large hypodermic needle. The needle should screw on to the syringe on account of the great resistance which has to be overcome in forcing the wax down the needle. The syringe and needle should be wrapped round with a spiral of iron wire which is attached to the galvano-cautery snare, by means of which the whole needle and syringe can be kept hot and the wax prevented from solidifying, as was originally suggested by Walker Downie. I keep the wax melting in a water bath and fill the syringe (previously thoroughly warmed over a spirit lamp) and then screw on the needle The patient's nasal mucous membrane should as far as possible be rendered anæsthetic by cocaine or eucaine The needle is inserted so as to allow of its being pushed along under the mucous membrane of the inferior turbinate, or what remains of the structure, according to the degree of atrophy present. As much paraffin is now injected as possible, the wax being kept fluid by heating the wire attached to the galvano-cautery snare The needle may be withdrawn after waiting for about one minute to allow the wax to set In very suitable cases I have replaced the turbinate with one injection of about 25 minims of melted wax In other cases it is necessary to inject several minims every week.

As a result of the restoration of the turbinate in these cases the patients express themselves as being far more comfortable, of feeling the air passing through their noses, and the formation of crusts has not recurred in cases where it had been checked before injecting and the crust formation has been more rapidly checked in cases where it was still present. Whatever the origin of this most obscure disease really is I firmly believe that in this treatment we have a means of assisting to check its progress if used sufficiently early and of restoring to relative comfort many of those in whom the disease is well established and whose nasal cavities have lost all resemblance to the normal.

Harley-street W

THE VARIABILITY IN VIRULENCE OF THE PNEUMOCOCCUS

BY H SINIGAR, M D, B S LOND, D P H, &C.,
MEDICAL OFFICER, MARYLEBONE SCHOOLS SOUTHALL LATE SENIOR ASSISTANT MEDICAL OFFICER, LEAVESDEN ASYLUM

THE late Dr J W Washbourn in the Croonian Lectures on the Natural History and Pathology of Pneumonia[1] referred at length to the variability in the virulence of different strains of pneumococci and quoted numerous illustrative experiments by himself and others. One would expect, however, an organism grown artificially with such difficulty as the pneumococcus to show great variability in laboratory experiments. I therefore thought that a short account of an epidemic which occurred last winter amongst the staff and patients of Leavesden Asylum would be of interest, as it seems to me to furnish clinical evidence of variability in virulence of the pneumococcus under natural conditions.

The first case which attracted attention was that of a male patient whose illness dated from Nov 30th, 1901, when a left basal pneumonia commenced. I saw him after he had been ill about three weeks and he then still had signs of consolidation of the left lower lobe. His general condition was bad and a microscopic examination of his sputum, which was frothy and muco-purulent, was made. No tubercle bacilli were found, but there were large numbers of capsulated diplococci present, which in their staining and morphology presented all the characters of the pneumococcus of Talamon-Fränkel. The man remained in an asthenic condition, his cough persisted, and the physical signs at the left base did not improve. Film preparations of his sputum were frequently examined, crowds of pneumococci were always found, and tubercle bacilli were always absent. A month later it was noted that the pneumococci began to assume a streptococcal character in that long spiral chains, containing 20 or more cocci, occurred, the diplococcal nature of the elements of the chain could, however, always be demonstrated.

On Jan. 7th, 1902, sickness appeared amongst the male attendants, the symptoms in the early cases consisting of headache and pains in the back and limbs, accompanied by a slight rise of temperature. The acute symptoms lasted two or three days and much resembled ordinary catarrh. Several cases occurred within a few days and it was then thought that an epidemic of influenza was beginning These early illnesses were certainly very like the indefinite cases of influenza so common in recent years but prostration was not very marked and convalescence was rapid and uneventful There was little or no cough in the earliest cases, but pharyngeal and bronchial catarrh were common in the later cases, with expectoration of scanty and viscid mucus, in which on examination pneumococci were found in large numbers, whilst influenza bacilli were never discovered Sickness next appeared amongst the female attendants and in the majority of cases the illness was of an influenzal type. Cough was now a more frequent symptom and the expectoration from these cases, scanty and viscid, was likewise found to contain no influenza bacilli but was swarming with pneumococci. Examination of the chest revealed no definite signs in the early cases, but signs of bronchial catarrh were found in most of the later cases, one nurse, however, had a small area of pneumonic consolidation and another—one of the last nurses to be attacked—developed a typical apical pneumonia which ran an ordinary course and from which she convalesced well.

At the end of January the female patients were attacked, six women becoming suddenly ill with rise of temperature, pains all over, and marked prostration. One case began with a rigor one with vomiting and another with profuse diarrhœa. Three of the women first attacked developed a cough with frothy sputum, and in these cases resonance was impaired and coarse crepitations were heard over the bases of the lungs. During the next week four fresh cases occurred, in all the onset was sudden, in three of the cases there were physical signs of patchy consolidation of the lung whilst the fourth was a true lobar pneumonia which was followed by empyema and was fatal In the next week 20 cases occurred, 15 of which were cases of lobar pneumonia, the remaining five cases consisting of a short pyrexial illness with pains in the back and limbs slight cough, and signs of bronchial catarrh, even in two of these instances resonance was impaired over the bases and the respirations were quickened. Of the 15 cases of pneumonia 12 were fatal. In the next week 13 women were attacked, nine being cases of lobar pneumonia with four deaths, whilst the other four were ill for a few days only with pains and rise of temperature. During these three weeks several cases of illness, exactly similar in all respects occurred amongst the male patients, six of whom died from pneumonia.

The epidemic subsided suddenly at the end of February Frequent microscopic examinations of sputum from many of the cases were made and in every preparation pneumococci were present in large numbers, smear preparations of the lungs from the fatal cases and also from the pus in the case of empyema, showed the same result. The gradually increasing severity of the cases was very marked, the maximum virulence being reached about the middle of February when one woman, previously strong and healthy became unconscious in 24 hours and was dead within 48 a moist swab or sponge must be passed over the film when it becomes at once transparent.

---

[1] THE LANCET Nov 15th, 1902, et seq

When the film is to be removed it is only necessary to place a wet cloth or swab upon it for one or two minutes , if one corner of the film be then raised the whole can be peeled off with ease This, as a rule, can be done with perfect ease on the fifth day, when the edges of the wound will be found to be perfectly united and the sutures can be removed A very noticeable point when the film is removed is the perfect manner in which the edges of the skin have united and the clean appearance of the skin round the scar which is represented by a purple streak about the one twentieth of an inch in diameter In some cases there may be considerable effusion of blood between the film and the wound, but in few cases has this made any difference to the rapid and perfect healing of the wound.

If a drain is inserted in the wound it is as well to place it at the lower end of the incision and then to apply an absorbent sterile dressing over it. A much better plan is to make a separate skin incision for the drainage tube or plug of gauze as far from the wound as possible In some situations it is not possible to exert much or any pressure on the wound In such circumstances there may be a large amount of blood plasma or serum collecting beneath the film, but much more commonly beneath the skin This has occurred in a few of my cases, but the fluid has generally been absorbed in a few days and has only necessitated the film being left on for a few days longer

It may be said that such a film dressing is inapplicable on uneven surfaces, as, for example, the axilla after an operation for removing glands, but with a little manipulative dexterity it will be found to be easy of application even here and much safer than the ordinary dressing

When the sutures have been removed from the wound it should be washed with carbolic lotion (1 in 40) followed by a little acetone to remove the water Each stitch hole may then be painted over with a little velvril solution. It is safer again to apply wool and bandage to protect the scar from injury for a few days. In the case of a perfectly dry wound the film may be left exposed to the air It is, however, safer to apply wool and bandage as the patient is apt to scratch his wound while he is semi conscious from the effects of the anæsthetic. As a rule the patient feels none of that irritation which is often experienced during the healing of a wound under an ordinary dressing

Though various kinds of films have been used for dressing wounds I believe that it has never been possible to keep a wound hermetically sealed for any length of time with any of them I have elsewhere[2] pointed out that alcohol applied locally to a wound possesses several marked advantages over other germicides more generally in use , its power of checking capillary oozing is only one of them. When a velvril film has been applied to a small wound which is bleeding freely according to the method above indicated, some blood will escape from beneath the film for a few minutes in some instances This is due to the fact that the solution and the film in contact with it have not had time to adhere to the skin and wound. If, however, pressure be steadily maintained for a few minutes the film will, even in such disadvantageous circumstances, be found to adhere firmly and to remain adherent. I have verified this over and over again in the case of small wounds on my own hands and it has always succeeded perfectly well. I have had some remarkable results when experimenting with the solution and film in the case of septic wounds, such as abscesses, boils, &c , all acute inflammatory conditions seeming to abate very rapidly under the influence of the substance. Whether these results are due to the solvent, to the velvril itself, or to the exclusion of air, I have not determined I hope to refer again to this matter at a later date. I must thank Mr Reid and the Velvril Company for the help which they have given me while experimenting with velvril and for the amount of trouble which they have taken in preparing it in the form of films ready for use surgically

Velvril is a very remarkable substance and I think it may soon entirely supersede protective (oil silk) thin mackintosh and gum elastic in surgical practice. In commerce it is now being used very largely for a great number of different purposes and in various trades It is practically indestructible and constant in composition at all ordinary temperatures

Grosvenor-street W

THE RESTORATION OF THE INFERIOR TURBINATE BODY BY PARAFFIN INJECTIONS IN THE TREATMENT OF ATROPHIC RHINITIS

By R. LAKE, F R.C S Eng ,
SURGEON LARYNGOLOGIST TO THE MOUNT VERNON HOSPITAL FOR CONSUMPTION SURGEON TO THE ROYAL EAR HOSPITAL.

In the early part of 1902 I showed before the Laryngological Society of London[1] a case of bilateral atrophic rhinitis in which the inferior turbinate bones which had undergone absorption had been restored by the submucous injection of melted paraffin wax. Two months later Brindel of Bordeaux showed a series of ten cases which had been treated by the same method Since then I have treated several cases successfully, others with partial success. In August, 1902, a paper was communicated to the Belgian medical press by Dr P J Mink of Deventer, in which he details a series of very interesting experiments demonstrating the function of the inferior turbinate bone and its importance in respiration At the conclusion of the paper Dr Mink remarks that the value of the inferior turbinate was so great and its importance in the economy so marked that he considered it might be necessary to attempt to replace this structure when destroyed by disease—as, for example, in cases of atrophic rhinitis. On seeing a report of my case Dr Mink very kindly drew my attention to his paper It is entitled "The Nose as an Air Passage,' and in it he points out that in normal circumstances the pressure in the naso-pharynx during respiration is equal to a column of about eight cubic millimetres of water , whilst anterior to the turbinates the pressure is only four millimetres , and that after cocainisation of the inferior turbinate the pressure in the naso-pharynx falls to four cubic millimetres. From this he drew the conclusion that the inferior turbinate should be considered to exert a physiological resistance during expiration. He considered that such a resistance was extremely valuable in the oxygenisation of blood in the lungs, because the value of an expiration depends on its duration and to some extent on the resistance. This opinion he bases on the experience of Valentine who found that the relations between CO_2 and O in the expired air become raised from 1 1 18 to 1 1 31 when a normal expiration is replaced by a very short one. It was for these reasons he deprecated the removal of the inferior turbinate and expressed the above mentioned opinion as to restoring it

I had not made any experiments myself with regard to the value of the inferior turbinate bone from the point of view of the general physiology , I had worked upon the theory that the absorption of the inferior turbinate bones was not entirely due to atrophic rhinitis *per se* but that the formation and shrinkage of the crusts which are so freely formed in this disease were largely instrumental in the destruction of these bones and that if this body were restored by the injection of paraffin it would resist crust formation should that still continue. If however, the crust formation had been checked these artificial turbinates would remain and serve at least some useful purposes. These were that, by reducing the nasal passage to its normal width the patients would again be aware of nasal respiration being carried out, the loss of which sensation is often severely felt by them, and at the same time this constriction would render the removal of discharge by irrigation easier and enable the air current to exercise its physiological benefits on the nasal mucosa, for I believe that the friction caused by the passage of air through the nose is most beneficial in maintaining the parts in their normal condition. To these Dr Mink has now added a third theoretical reason and we have the testimony also of Brindel as to the value of the treatment. Brindel's work in this matter was not only independent of mine but probably even commenced earlier, and it was accident alone which caused my case to appear first in the medical press Brindel states in his report that there are certain cases in which he has been unable to inject the paraffin I have also found these cases. They are cases in which the disease is well advanced, in which there is practically no obstruction to the flow of blood in the capillaries beyond. He thought that this condition of rise of blood pressure was not confined to the later period of life, for it was not infrequently seen in the schoolboy and often in men under 30 years of age. He said that in a large majority of cases of high blood pressure there was no kidney disease and he was of the opinion that it was a blood condition which gave rise to the resistance in the peripheral vessels and also to the renal disease. When however the renal disease was established the condition was accentuated, since toxic substances failed to be excreted by the kidney The peripheral resistance was often due to contraction of the muscular fibres in the small vessels and this was well shown by the immediate effect which was produced by nitro-glycerine He then referred to the effects of syphilis on the arterial system and said that the disease affected the larger and smaller vessels at the same time, he thought that aneurysms were rare in Bright's disease and in cases of high arterial tension which were independent of syphilis.

---

[2] Phonograph Record of Clinical Teaching in 1898, vol iv , p 138.

[1] Transactions of the Laryngological Society of London March, 1902.

Dr ALEXANDER HAIG said that some years ago he had made experiments of injecting uric acid into animals but the results had always been indefinite. From 15 to 20 grains were injected into animals and then the whole of the blood was collected When the uric acid was estimated in this it was found that there was no increase over the amount normally present The probable explanation of this fact was that the uric acid was taken up by the liver He stated that the return of circulation in the skin after pressure was twice as slow in a person on meat diet as it was in a person on a vegetable diet, and this fact showed that there was a contraction of the finer vessels.

Dr G NEWTON PITT said that he thought it was generally recognised that high arterial pressure preceded arterial degeneration and cardiac hypertrophy In a case of chronic Bright's disease the nitrogen in the ingesta and excreta had been carefully investigated by Dr H. S. French and had been found to be practically equal It would seem therefore that the vascular degeneration could not be due to an increased nitrogenous substance in the blood.

Dr H. D ROLLESTON said that among the interesting questions raised by Professor Allbutt two were especially important. First, the relation of high blood pressure to arterio-sclerosis, which had already been fully dealt with, and secondly the relation of kidney disease to arterial disease. No doubt tubal nephritis might lead to increased blood pressure and so to degeneration of the muscular coat and the compensatory process of chronic endarteritis The gradual alteration of a large white kidney into a small white kidney was due to arterio-sclerotic changes in the vessels which diminished the blood supply to certain portions of the kidney substance and fibrosis resulted in those portions from which the blood had been cut off.

Professor ALLBUTT replied.

MEDICAL SOCIETY OF LONDON

Suppression of Urine in a Case of Ovarian Tumour and Pregnancy —Etiology of Emphysema from the Physical Standpoint.

A MEETING of this society was held on Jan 12th Mr. A. PEARCE GOULD the President being in the chair

Mr H. B BOULTER (Richmond) presented to the society the Fothergillian medal awarded to the late Dr Robert Willan in 1790, which had been given to Mr Boulter for presentation to the Medical Society of London by a descendant of Dr Willan.—The PRESIDENT expressed the thanks of the society for this valuable and interesting gift, and remarked that this was the second Fothergillian medal awarded, the first was awarded in 1787 to Dr Falconer and the third was awarded in 1791 to Dr C Lettsom.

Mr BERNARD PITTS read the notes of a case of Suppression of Urine associated with Ovarian Tumour and Pregnancy He remarked that anuria in a case of non malignant tumour was very rare. The patient was a married woman aged 44 years, who had had seven children. About three and a half years before the operation a lump appeared in the abdomen and gradually increased in size. When she consulted Dr M. C Ward about three years later the tumour had increased immensely being hard in some parts and fluctuating in others. The patient subsequently became pregnant and the symptoms more urgent After admission suppression of urine gradually supervened and finally the urine became completely suppressed for some 36 hours Mr Pitts operated and found a large multilocular ovarian tumour It was necessary to remove the uterus in order to effect the eradication of the tumour The urinary secretion was at once restored and the urine gradually became normal both in quality and quantity The pressure of the tumour had evidently been directly upon the kidneys in the upper part of the abdomen The real interest of the case depended upon the anuria which complicated the case, and Mr Pitts discussed the causes of anuria other than pressure on the ureters.—The PRESIDENT said that there could be no doubt that the right line of treatment had been adopted and he approved the extra peritoneal method of hysterectomy in this case As to the cause of the anuria, he suggested that it might have been due to pressure both on the kidneys and on the ureters and renal vessels—Dr WARD remarked that he had known the patient for some years and noted the fact that she had been at work up to a few weeks before the operation almost without inconvenience He believed that the tumour removed, together with the uterus, weighed some 85 or 90 pounds.

Dr B J COLLINGWOOD made a communication on the Etiology of Emphysema from the Physical Standpoint. An attempt was made in this paper to bring about a compromise between the expiratory and the inspiratory theories of the causation of emphysema. It was suggested that emphysema in the protected parts of the lungs was due to inspiration and in the unprotected to expiration. Two causes were given for the production of the disease in both the protected and the unprotected parts—namely, weakness of the elastic tissue of the lungs and over straining of the elastic tissue. Both causes resulted in the production of a vicious circle, for either weakness or over straining of the elastic tissue would lead to its over distension and consequent further weakening The following facts were adduced in support of the view that emphysema in the protected parts of the lungs was due to inspiration (1) the position of the chest in emphysema was one of extreme inspiration, a result which could not be brought about by any form of expiration, (2) emphysema was a markedly progressive disease, but if it were produced by expirations the further emphysema advanced the less power would they possess, for more and more difficulty was experienced in producing expiration, and (3) emphysema was more marked at the periphery than at the centre of the lungs, but the periphery was the part most directly compressed by expiration. It was pointed out that violent expiratory efforts against an obstruction could not produce emphysema in protected parts of the lungs, for during such efforts the protected parts were slightly contracted. Although it was difficult to decide which parts of the lungs were unprotected yet it was certain that such parts formed only a small proportion of the whole lung A general emphysema accordingly must be mostly inspiratory in origin. Compensatory emphysema was stated to be due to inspirations of normal depth but excessive strength, causing hyperdistension of the pulmonary infundibula when some neighbouring infundibula owing to disease were incapable of expansion. Experiments were shown illustrating this as well as other points in the communication. A method of treatment for general emphysema was suggested which consisted in supplying some elastic support to the thorax. It was urged that this would prove beneficial by aiding expiration and preventing excessive inspiration —Dr P HORTON SMITH congratulated Dr. Collingwood upon his painstaking researches. The combination of the inspiratory and expiratory theories of emphysema explained many of the clinical facts observed in that affection which one of them alone could not. The causal explanation appeared to him to differ in the protected and unprotected parts of the lung —Dr A. G AULD could not altogether agree with the inspiratory theory suggested by Dr. Collingwood, and he referred to 'glass blower's emphysema.' He could not believe that experiments with an indiarubber bag could be made to reproduce all the conditions of the pulmonary alveoli.—Dr H. A. CALEY remarked that they must differentiate between the protected and the unprotected parts of the lung It had always appeared to him that the commonly accepted expiratory theory could not explain the occurrence of emphysema in both the protected and in the unprotected parts of the lung The dual theory appeared more reasonable. He had seen Dr Collingwood's experiments in the laboratory with rabbits lungs and they had produced hours of the onset of her illness So densely crowded were the pneumococci in films made from the sputum in this case that it seemed reasonable to assume that quite an appreciable part of her sputum must have consisted of pneumococci.

It was not possible to make microscopic preparations from every patient, but pneumococci were present in large numbers in all the cases examined The virulence of the pneumococci from the early cases of illness amongst the staff was not tested, but a mouse inoculated with sputum from one of the patients at the end of January died in 18 hours from pneumococcal septicæmia. Although the chain of evidence from a bacteriological point of view is not absolutely complete, yet the sequence of events was so very definite that we felt convinced that we were dealing with a pneumococcal epidemic amongst the staff, at first of low virulence, causing a short indefinite illness much resembling influenza, gradually increasing in severity, and then causing a more protracted illness with occasional bronchial symptoms and culminating in a case of lobar pneumonia in a nurse By the time the female patients were attacked its virulence was such that pulmonary symptoms were most in evidence and the short vague illnesses were few, even at this time, however, the pulmonary signs were those of patchy consolidation only When the maximum virulence was reached most of the cases were true lobar pneumonias with a high mortality Altogether 13 nurses, 17 male attendants, and 43 female patients were attacked, the exact number of male patients attacked was not recorded A careful investigation failed to reveal evidence of direct contagion amongst the female patients

To Leavesden Asylum the epidemic is, I think, of great importance, since for the past few years tuberculosis has been rife amongst the patients of that institution It is easy enough to imagine how well last winter's epidemic will have prepared the soil for the tubercle bacillus, for in the majority of the non fatal cases tardy convalescence, with delayed and incomplete resolution of the lungs, was noted.

Another point of interest lies in the short vague illnesses which occurred all through the epidemic but which especially characterised its early stages. Everyone is familiar with the short illness which is so glibly called "influenza," and which every medical man knows is not influenza Is it not possible that the pneumococcus may be the cause of some of these illnesses? We assume that a non pathogenic organism can acquire virulence under certain conditions with which we are not yet exactly familiar, if that is true, it is not unreasonable to assume that there may be a transition stage of moderate virulence, and it seems to me quite possible that the pneumococcus, in the course of its transition from a harmless resident of the mouth or nose to a virulent pathogenic organism, may exist for a time as an organism of moderate pathogenic powers, and whilst in this state may be capable of causing an illness such as occurred at the commencement of this epidemic.

I have to thank Dr F A. Elkins medical superintendent of Leavesden Asylum, for permission to record these facts, and Dr J F Rimmer for bringing the cases of illness amongst the staff under my notice.

Southall.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Rise of Blood Pressure in Later Life

A MEETING of this society was held on Jan 13th, Mr ALFRED WILLETT, the President being in the chair

Professor T CLIFFORD ALLBUTT read a paper on the Rise of Blood Pressure in Later Life He said it was inevitable that in the growth of medicine a static morbid anatomy should precede the study of morbid processes or clinical dynamics. Nevertheless, occupation with the ruins of the dead body for a time took observers away from origins to consummations and created a certain fatalism in medicine The revolution in thought which followed the publication of "The Origin of Species" extended its influence into pathology, diseases began to lose fixity of form in the mind of the physician, and the hope of detecting and neutralising morbid processes at their sources relieved the despair of the dead house Of certain early deviations from the true balance of functions it might be said that, if they did not arise primarily in the circulation, yet that in this system the first evidence of them might be perceived Of such evidence the fluctuations of arterial blood pressure were very important. In the present paper changes of pressure in the direction of increase would be considered and that mode of it which in many elderly persons was apt to be persistent The rise of pressure in Bright's disease was perhaps the best-known instance of such a rise, but the change was by no means confined to that disease. Some degrees of fibrosis of the kidneys, as of other parts, were to be found in a large majority of necropsies upon elderly persons, but "granular kidney" had peculiar clinical characters and must have its own niche in nosology It was generally assumed that arterial disease was necessarily attended with a rise of blood pressure, many kinds of arterial disease being comprehended or confused under the title "arterio-sclerosis" Such was far from being the case, it was not true of many of the acuter affections of the arterial tree, and in many of the more chronic, even of the involutionary kind, however extreme, a high blood pressure was conspicuously absent. The more senile forms of arterial disease might then be divided, from the present point of view, into those in which pressure was raised and those in which it was normal or even low The first kind—those with high pressure—tended to death by apoplexy, the latter tended, often after length of years rather to obliterative changes in the cerebral arteries with softening Pressure must depend upon two antecedents, singly or in combination—namely, diminution of the calibre of the arterial system and increased viscosity of the blood, it was not proved, or even probable, that loss of elasticity in the vessels always or generally led to loss of capacity Encroachment upon capacity in some areas was apt to be compensated by dilatation in others. Professor Allbutt suggested that the tendency to rise of pressure, often seen in elderly persons, especially in such as had led a sedentary life with positive or relative excess of food, depended on increase of viscosity of the blood Circumstances had hitherto defeated his attempts to gauge the viscosity in a series of appropriate cases. In contrast with the rising pressure of many elderly men might be set the low pressures in the young and athletic. In temperate and active men under 30 or 35 years of age the pressure ranged from 95 to 105 millimetres Hg (Hill and Barnard's sphygmometer) If the opinion here expressed that the arterial tree was prone to be "self strained," and that arterio sclerosis was a result rather than a cause of high pressure, the tendency to such rises and their causes should be watched There was no definite reason to allege that a rise of this kind was to be regarded as of the nature of gout, whatever gout might be, though it might well depend on some perversion of assimilation or excretion having an affinity to gout If the morbid tendency to rise of pressure was detected in time the disposition was remediable, chiefly by deobstruent, dietetic, and gymnastic means, some such change of habits of life being of course permanently imposed upon the patient, if, on the other hand, it was not detected till the strain had resulted in a new "set" of the vascular tissues, if palliation was possible cure was out of the question Hitherto it had been difficult to measure blood pressures, and finger estimates very properly had not commanded a ready acceptance, the personal equation of the observer entered too far into such observations Now, however, they had useful instruments for the purpose invented by von Basch, Hill and Barnard, and Oliver, Professor Allbutt had used that of Hill and Barnard.

Sir WILLIAM BROADBENT said that in general he was in agreement with the paper, though he considered it necessary to have some definite understanding of what was meant by the rise of blood pressure in later life. Professor Allbutt had noted the marked effect which emotion had in producing a rise of blood pressure and there were many other conditions which temporarily produced a like effect. The registration of the blood pressure in the radial artery would not distinguish between a fugitive and permanent rise of pressure, as, for instance, in the two conditions aortic regurgitation and advanced arterial disease The real cause of high blood pressure was the obstruction to the flow of blood in the small arteries or in the capillary network. He considered that the obstruction was probably in the capillary network and he knew of no other explanation for the occurrence of miliary aneurysms of the smaller arteries unless they were produced by the or alcohol in this case.—Dr GOODALL, in reply, observed that such cases were fortunately rare, seeing that they usually proved fatal. He thought alcohol could be excluded in his case, and it was not given medicinally until long after the symptoms had developed.

Dr H. D ROLLESTON read the notes of a case of Generalised Miliary Tuberculosis with Acute Synovitis. The patient was a man, aged 52 years, who was admitted to St George's Hospital, after two weeks' illness with a temperature of 103° F, in a semi-delirious condition, and with painful and swollen joints At first, under salicylates, the pain diminished and the temperature fell, but shortly this effect was lost There were no physical signs of any importance, except widespread tenderness, and the patient became more prostrate and delirious and died five days after admission. The diagnosis during life lay between generalised tuberculosis, severe typhoid fever, and some pyæmic state The general condition suggested tuberculosis, but the arthritic manifestations made some other form of hæmic affection more probable. At the necropsy, except for synovitis, nothing definite was found, no tubercle could be seen Pieces of the lungs and spleen after being hardened, were seen, even by the naked eye, to be riddled with miliary tubercles. The association of generalised tuberculosis with acute synovitis of several joints was a very rare condition and might lead to an erroneous diagnosis of acute rheumatism. Another point of clinical interest was the widespread tenderness.—Dr J KINGSTON FOWLER mentioned the case of a girl who had a cavity in one lung and who suddenly developed acute synovitis of the wrist-joint. He thought that in Dr Rolleston's case there must have been some other concurrent affection because if the joint affection were really due to tuberculosis they would expect to meet with it more frequently

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN

Discussion on Tuberculous Peritonitis

A MEETING of this society was held on Dec. 12th, 1902, when Tuberculous Peritonitis was discussed, various portions of the subject being introduced by various speakers

Dr EDMUND CAUTLEY touched lightly upon numerous questions, from the liability of the individual to invasion by the tubercle bacillus to the special modes of entrance of the bacillus into the peritoneum. The speaker remarked that since the tubercle bacillus is so extremely common a vulnerability to the microbe must play as important a part in the etiology of the disease as exposure to the possibility of infection. A farmer did not erect screens to keep out the seeds of weeds, he cultivated his land in a way which was ill suited to their growth. To fortify the body, therefore, by good food and good clothing was as necessary as more direct war against the tubercle bacillus How far peritoneal tuberculosis might be due to invasion by the bacillus of bovine tuberculosis Dr Cautley considered to be still an open question.

Dr THEODORE FISHER (Bristol) followed with a few facts in connexion with the morbid anatomy gathered from examination of the post-mortem records of 80 cases which clinically had been examples of abdominal disease. He prefaced his remarks by saying that although he did not doubt that tuberculosis might arise primarily in the abdomen it was easy to overlook a single diseased bronchial gland, and he gave instances of early infection of the abdomen where the only tuberculous focus which could be found was a solitary caseous lymphatic gland lying hidden in one of the lungs Of the 80 cases examined the adhesive variety proved to be by far the most common in the post-mortem room, though in many of these at some time of life fluid had been present. Suppurating caseous masses had opened into the intestines in eight cases and in five others ulcers had perforated. Localised collections of fluid were present in five instances, and in two of these there had been discharge of the fluid at the umbilicus. In only two instances was it stated that the great omentum was sufficiently thickened to have formed a tumour Intestinal ulcers were present in about half the cases. The Fallopian tubes or ovaries were diseased in five cases of adult women but the majority of instances were in young children. Although cases did not appear to be common in the post-mortem room where after middle life evidence of old extensive tuberculous disease of the peritoneum was present, if one could argue from analogy the frequency with which general adhesion of a pleural cavity of tuberculous nature was found after middle life would lead one to think that when the disease was limited to the abdomen recovery might be permanent. In these 80 cases the lungs were free from disease in 17 and the tubercles were limited to the pleuræ in seven. Although in the remainder the lungs were diseased in some the lesions were recent and those of older standing were not often extensive.

Dr W C CHAFFEY (Brighton) gave a few of the results of an analysis of 118 cases of tuberculosis in children Tubercle of the peritoneum was present in 45 Of these 45 cases the disease was chronic in 22, in 13 of these 22 chronic cases intestinal ulcers were present and in 17 the lungs were diseased. In the 23 cases of recent tuberculosis of the peritoneum the lungs were affected in every instance

Dr JAMES BARR (Liverpool) then dealt with the diagnosis The most striking feature was swelling of the abdomen, which, however, might be moderate in degree. Pain was generally absent in the early stages, but there was occasionally some tenderness At first the appetite might be good and there might be little indication of ill health, but as the abdomen increased in size the appetite was lost, the patient wasted, and colicky pains associated with constipation might be added, which pains, however might be removed by diarrhœa, only to return with a return of the constipation. The temperature rarely rose above 101° F and might be normal or subnormal in the morning These remarks applied especially to the ascitic variety In the adhesive form there were various degrees of resistance to be felt in several places over the abdomen and the thickened omentum as a sausage-shaped mass might occasionally be felt. Localised collections of fluid when present were generally in the lower half of the abdomen In cases in which emaciation had been very marked improvement rarely took place, but Dr Barr had seen recovery after the bursting of an abscess at the umbilicus and also in a case when a fæcal fistula had formed in the same situation. At times there might be difficulty in differentiating tuberculous peritonitis from typhoid fever from ascites associated with cirrhosis of the liver, or from a simple chronic peritonitis. As a rule, however, patience and careful observation soon settled the diagnosis, but Dr. Barr had found injection of some of the peritoneal fluid into guinea pigs to be useful

Dr GEORGE CARPENTER had seen a large number of cases of tuberculous peritonitis and briefly referred to many He laid especial stress upon the value of combined rectal and abdominal examination as an aid to diagnosis in doubtful cases

Dr J PORTER PARKINSON remarked that on looking over the notes of 22 cases he had been struck with the somewhat rapid onset. The average history of 19 cases extended over three and a half weeks Dr Parkinson thought the occasional presence of enlarged veins over the upper half of the abdomen worthy of note and suggested some interference with the portal circulation An interesting case of colloid carcinoma of the peritoneum occurring in a girl, aged 12 years, was referred to which clinically could not be distinguished from tuberculous peritonitis.

Dr G A. SUTHERLAND then read a paper upon the prognosis of the disease. The following were his conclusions 1 In uncomplicated tuberculous peritonitis the prognosis was good 2 When tuberculous pleurisy was present the prognosis was still favourable. 3. The prognosis was rendered less favourable in the case of (*a*) a strong family history of tuberculosis, (*b*) an infancy passed under bad hygienic and dietetic conditions, (*c*) a constitution of feeble resistant power, and (*d*) a history of severe infective illness in early life. 4 The prognosis was rendered less favourable in the presence of one or more of the following symptoms continuous pyrexia, rapid wasting, persistent diarrhœa, rapid pulse, and recurrent acute exacerbations 5. The prognosis was rendered less favourable in the presence of one or more of the following local complications (*a*) tuberculous ulceration of the bowel, (*b*) extensive caseation of the mesenteric glands or of tuberculous masses, (*c*) localised suppuration from infection through glands or the intestine, and (*d*) obstructive symptoms from bands or matting of the intestine. 6 The prognosis was bad in the case of the following complications (*a*) rupture of a suppurating gland or the perforation of an intestinal ulcer into the peritoneal cavity, (*b*) pulmonary tuberculosis, (*c*) tuberculous meningitis, and (*d*) general miliary tuberculosis. 7 In tuberculous peritonitis the prognosis was not appreciably affected by laparotomy Much of the paper dealt with the last conclusion. At one time Dr Sutherland the same results as those now exhibited with india rubber balls He was disposed to lay great stress on primary degenerative changes in the elastic tissue of the lungs. While, as Dr Collingwood stated, the element of mechanical strain might be the exciting cause and impaired elasticity only a predisposing cause, it would appear that in many cases the predisposing cause—impaired elasticity—was pathologically the more important.—Dr COLLINGWOOD, in reply, said that he did not mean to imply that the only cause of emphysema was a diminished elasticity of the chest wall.

CLINICAL SOCIETY OF LONDON

The Morbid Anatomy and Treatment of Congenital Dislocation of the Hip Joint —A Case of Hæmorrhagic Typhoid Fever —A Case of Generalised Miliary Tuberculosis with Acute Synovitis

A MEETING of this society was held on Jan. 9th, Mr HOWARD MARSH, the President, being in the chair

Mr T H OPENSHAW, C M.G , made a communication on the Morbid Anatomy and Treatment of Congenital Dislocation of the Hip-joint, based on 70 cases which he had observed and upon nine of which he had operated. Mr Openshaw commenced by showing a recent specimen of congenital hip dislocation obtained from a girl, aged five years, who had died from bronchial pneumonia, which he described. The head of the bone was normal in shape with the exception of a small area of flattening at the lower end and back part The neck of the femur presented no abnormality These appearances entirely accorded with what Mr Openshaw had found by operation. In his experience, in every case an acetabulum existed, but it was small, shallow and triangular, and the cartilage forming its floor was thicker than normal. In his opinion, the head of the femur up to the age of three years remained normal It then became flattened at one part, and this flattening gradually extended over the whole surface, and thus the head of the bone became deformed and, as the result of subsequent osteo-arthritic change, it ultimately disappeared. The ligamentum teres he had hitherto considered to be absent, but, he added, it was quite possible he might have overlooked a thin flaccid band such as existed in the specimen which he submitted The children did not usually walk till the second year but no symptoms were noticed in them In some cases the condition appeared to be hereditary but the etiology was obscure Mr Openshaw advocated one of two methods of treatment (1) reduction of the shortening by tenotomy and extension and then reposition, so-called, of the head of the bone by manipulation as practised by Lorenz , or (2) the remaking of an acetabulum by the open method after it had become possible to replace the bone by tenotomy and manipulation. As the result of his experience in about 20 cases treated by the first method during the past six years he considered, first, that reposition within the joint was an impossibility, and, secondly that redislocation was exceedingly common. He strongly advised the two methods combined and showed two cases where he had operated with excellent results He pointed out that if the shortening was overcome first the shock of the operation was slight and a fatal result need never be anticipated, and that if any open operation were advisable that of deepening the acetabulum was the only one to be entertained —Mr J JACKSON CLARKE remarked that the specimen shown by Mr Openshaw resembled very closely what he had found in the newly born infant He had operated in about 20 cases by the Lorenz method and in only one instance had he failed to obtain a good result In some of the cases there seemed to be almost complete reposition allowing for the arrest of growth and the consequent inevitable shortening In the one case of failure the child was suffering from spastic paralysis which had not been recognised, so that the failure was explained.—Mr NOBLE SMITH pointed out that Lorenz, who had at first employed the open method of operation, had finally abandoned it Mr Noble Smith advocated the manipulative method dividing the operation into two stages, by which means he believed the amount of force required to effect replacement was much reduced. To retain the bone in its place plaster of Paris had several disadvantages and he advocated the use of an apparatus. He asked what proportion of Mr Openshaw's cases were due to breech presentation.—The PRESIDENT urged that in discussing this question they should bear in mind the various facts worked out in connexion with its pathology, and he called attention to a valuable paper contributed by Mr F F Burghard to the *British Medical Journal* in 1891, giving the results of his very exact anatomical investigations. That author referred to the hour glass contraction of the capsule which offered an obstacle to reduction and which was probably due to the ilio psoas tendon The head of the bone was often in an upper pouch of the capsule, above the acetabulum proper, from which it was shut off by an isthmus. Mr Burghard found that division of the ilio-psoas tendon allowed of the easy replacement of the head of the femur The President suggested that a committee should be appointed to investigate and to report on the subject, but he admitted that such a committee would be confronted with the difficulty of deciding what the condition had been before operation, so that it would be desirable for it to watch cases from the beginning He himself was not prepared to assert that in all Mr Openshaw's cases the head of the bone had really been returned into the acetabulum proper He did not believe in treatment by simple extension , the best result obtainable in many cases was bony ankylosis The subsequent history of these cases was often wanting He mentioned that he had once been called to see a young woman who turned out to be the very patient whose case had previously been extensively reported as an instance of cure by long extension at the hands of a late well known surgeon, but, as a matter of fact, it was clearly a case of unaltered unreduced congenital dislocation.—Mr OPENSHAW, in reply, maintained that it was not only the ilio-psoas tendon that was at fault, the capsule as a whole being contracted.

Dr E W GOODALL communicated a case of Hæmorrhagic Typhoid Fever The patient was a hospital nurse, aged 28 years After being out of sorts for a week she noticed on Jan 20th some purpuric spots on her legs and it was found that her temperature was 104° F Within the next few days a considerable number of purpuric and petechial spots appeared in the skin and subcutaneous tissue and there was bleeding from the fauces and gums, together with epistaxis, hæmatemesis, hæmaturia, metrorrhagia, and melæna. There was continued pyrexia but no rose spots and the spleen was not enlarged The patient gradually sank and died at the end of a fortnight from the appearance of the purpura. A post-mortem examination revealed typhoid ulcers in the small intestine and hæmorrhages into the stomach, peritoneum, bladder, and right kidney In the kidney were also a number of small yellow spots which under the microscope proved to be masses of round cells surrounding clumps of bacilli, probably bacillus coli. The blood gave only a feeble serum reaction An agar culture taken from the heart blood gave bacillus coli, while those taken from the spleen and a mesenteric gland gave bacillus coli and bacillus typhosus The case was reported because of the difficulty that attended the diagnosis and also because of its rarity The diagnosis made was acute bacterial infection perhaps streptococcal and it was not till two or three days before death that typhoid fever was suspected. The rarity of the case was shown by the fact that it was the only marked one of its kind in a series of 1733 cases of typhoid fever The pathology of these cases was obscure, probably the purpura was due to the action of bacteria or their toxins, in this case perhaps the bacillus coli In a similar case reported by Dr A G Nicholls and Mr G E Learmonth[1] in THE LANCET the organism concerned appeared to be the staphylococcus pyogenes albus. In the present case calcium chloride and adrenalin chloride were given without avail —Dr W LEE DICKINSON referred to two similar cases, both in confirmed alcoholics, reported by American authors, and mentioned one of the same kind which he had observed at St. George's Hospital The patient was a woman, aged 29 years, who bled from almost every mucous surface. He recalled the statements recently made by Dr A. E. Wright before the Royal Medical and Chirurgical Society to the effect that in the acute stage of typhoid fever the coagulability of the blood was hindered, whereas in the later stages it was abnormally increased, thereby disposing to the formation of clots That observer also stated that alcohol diminished the tendency of the blood to coagulate.—Dr W COODE ADAMS mentioned a case which he had observed during an epidemic in North London The patient developed patches of purpura over the limbs and trunk, but she recovered There could be no question of deficient nutrition never quite efficient and a slight stress might turn the scale, and (4) when cardiac enfeeblement was extreme and irremediable. In the first stage, as a rule, no treatment was necessary except a general warning against overstrain, but occasionally there might be excessive arterial tension or excessive pulse rate. Such symptoms might well be treated by the method to be described. In the second stage baths and exercises held the place of pre-eminence The earlier the treatment was begun in this stage, the greater the value of mechanical methods. In the third stage mechanical methods tended to become useless and finally were contra-indicated while drugs might still retain their potency The application of mechanico-balneological treatment by the family physician was advocated because he was more likely to see the patient at the time when it was of greatest value. Where cardiac dilatation and arterial tension were prominent relief must be afforded by arterial relaxation. In cases of less severity gentle stimulation might be adopted These effects could be brought about by varying the temperature, composition, and duration of the baths A temperature of from 92° to 95° F produced moderate dilatation of the vessels, with slowing of the pulse rate. When the temperature was lowered to 85° contraction of the peripheral vessels was caused, with great increase in the force of ventricular systole, the total effect being one of stimulation. The most useful constituents of the bath were the chlorides of sodium and calcium and carbonic acid gas. The greater the proportion of these the greater the stimulating effect. The duration of the bath should be longer when a sedative action was required. When the first indication was heart relief, to a bath of 50 gallons five pounds of common salt should be added and five ounces of calcium chloride, together with half the contents of one of Sandow's boxes The bath was to be given at 95° and lasted about 15 minutes, the patient then remained recumbent for two hours After a few days the temperature was gradually reduced to 92°, while the proportion of saline constituents was doubled As the patients improved stimulating treatment was introduced by lowering the temperature of the bath still further and increasing the added solids Very gradually the temperature of the bath was lowered to 85° and the strength of the saline solution was increased to 6 per cent. Beyond this it was rarely necessary to go Systematic exercises were chiefly of service in the early part of the second stage or when relief had already been obtained from baths They could be carried out without a specially trained assistant by the following method. Instead of the reversal of each exercise being a continuation of the initial part an intermediate pause was introduced. Thus the first portion was made to last 15 seconds, the part moved was retained in the position it had reached for five seconds and the reversal was made to occupy 15 seconds. In very muscular subjects extremely light weights might be placed in the hands. The pulse was counted immediately before the exercises and again after three minutes had elapsed, by which time its rate should have fallen This was the simplest test as to the prospective value of the exercises During the exercises the breathing should be even and continuous Instead of the Nauheim exercises a system of weights and pulleys might be used. At the end of a series of exercises it was well to examine the area of cardiac dulness and the position of the apex beat If the area of dulness was enlarged it might be taken that the dosage was too high The cases which benefited most were those of moderate dilatation accompanied, and in great part caused, by general malnutrition. Cases presenting minor degrees of arterio-sclerosis might be accepted for treatment. In supposed cardiac neuroses, such as tachycardia and arhythmia, the patients often did well There were many failures among elderly persons Cases in which the imagination alone was at fault should not be treated as they certainly detracted from the reputation of the method.—Dr O W Chapman said that the patients suitable for Nauheim treatment were (1) convalescents from acute cardiac disease after prolonged rest had been taken, (2) patients presenting cardiac symptoms, but devoid of organic disease, (3) patients in the early stages of cardio-vascular degeneration, and (4) the large class known as neurotics. The treatment was contra-indicated in (1) all advanced cases of heart disease, (2) marked cases of cardio-vascular disease, especially with albuminuria, and (3) the labouring classes who required rest above all things.—Dr A Morison, Dr F H Alderson, and Dr A J R Oxley also spoke.—Dr Otto F F Grünbaum read a paper on the Value of Examination of the Blood as an Aid to Diagnosis and Prognosis He said that an increase in the number of white cells accompanied many forms of malignant disease, nearly all fevers, and extensive formation of pus but when pus was present there was generally also an increase in blood platelets and in the amount of fibrin In certain doubtful cases of syphilis the method introduced by Justus might assist the diagnosis Justus found that in this disease, as soon as the lymphatic glands were affected, the intravenous or intramuscular injection of mercury caused the disintegration of a considerable number of red cells This disintegration was detected by estimating the hæmoglobin of the patient's blood. When the reaction to the injection was positive a fall of from 10 to 20 per cent of hæmoglobin would be noted within 48 hours, returning to the normal a few days later After a few injections the percentage ceased to fall and ultimately it might actually increase. The reaction did not occur when mercury was given by the mouth Cryoscopy, or the estimation of the freezing point of blood, might be of use in supplying information as to the state of the kidneys. In renal disease the quantity of salts and of urea in the blood was greater than normal. The greater the amount of these substances in the blood the lower would be its freezing-point. The average freezing point of normal human blood was – 0 56° C, if it fell to – 0 6° C, or lower, grave doubts as to the efficiency of the kidneys must be entertained Reference was also made to the estimation of choline in the blood, to agglutination reactions, and to the examination of the blood for micro-organisms It was also pointed out that, except in leukæmia and certain parasitic diseases no diagnosis could be founded on the examination of the blood alone.—Dr A. Whitfield said that he had used Justus's test in a number of cases of syphilis and had only found it fail once. He instanced a patient in whom the symptoms were so slight that diagnosis was not easy Finding that a drop of from 12 to 15 per cent. in the hæmoglobin took place in 24 hours after inunction with mercury he adopted the usual treatment. There was ultimately a very severe attack. The test was only of use in cases which had reached general constitutional infection and had not recently been under treatment with mercury

---

[1] THE LANCET Feb 2nd 1901 p 305

BRITISH GYNÆCOLOGICAL SOCIETY—The annual meeting of this society was held on Jan. 8th, Sir J Halliday Croom the President, being in the chair—The Fellows elected to succeed the retiring officers were as follows —President Dr Heywood Smith Vice-Presidents Mr E Stanmore Bishop, Dr H Macnaughton-Jones, Dr J A Mansell Moullin Mr Christopher Martin, and Dr F F Schacht Members of the council Mr G Roe Carter, Dr Eber Chambers, Sir J Halliday Croom, Dr F Edge, Dr Clement Godson, Mr A W Mayo Robson Mr Charles Ryall and Dr B T Smith Secretary Dr S Jervois Aarons—Dr J J Macan read his report upon the journal of the society, which was accepted with the thanks of the society to him for his services as editor—Dr Macnaughton Jones read notes of cases of (1) Binovular Pregnancy and Birth of Female Twins after Salpingo-oöphorectomy and Resection of the other Ovary, and (2) Repeated Pregnancies after Salpingo-oöphorectomy and Ventrofixation of the Uterus The patient had two uncomplicated labours, the children being healthy, but a third pregnancy ended in a miscarriage.—Dr Heywood Smith and the President commented on the cases—Dr William Duncan exhibited a very large Sarcoma of the Uterus removed by abdominal hysterectomy eight years after an uncomplicated menopause, the tumour detected ten years previously, had increased gradually till six months before the operation when rapid growth took place with loss of flesh and strength in the patient At the operation a cavity was opened from which escaped a clear odourless fluid, being taken to be a cyst it was freely incised but it proved to be the urinary bladder, drawn about three inches above the navel by the tumour The incision was closed by a single layer of silk sutures supplemented by a few finer stitches through the peritoneal coat, and the fundus of the elongated organ was fixed to the abdominal wall just above the pubes The tumour after much difficulty was got out of the abdomen and amputated When the posterior layers of the broad ligaments had been united from behind forwards a cavity as large as an adult head was left above the small cervical stump, this cavity was marsupialised to the lower part of the abdominal wound and lightly packed with gauze. Little blood was lost and the patient stood the operation, which lasted an hour and three had been an advocate of laparotomy, but further experience had convinced him that it had no effect upon the course of the disease More cases had recovered at the Paddington Green Children's Hospital under medical than under surgical treatment.

A communication from Dr JAMES CARMICHAEL (Edinburgh) stated that there had been only nine deaths in 48 cases which had been under his care, 13 of these cases had been kept under observation for a prolonged period and remained in good health.

Dr ROBERT HUTCHISON thought that a clear distinction must be drawn between cases where the disease was limited to the abdomen and those in which it was more widespread Possibly the abdominal tuberculosis might be bovine in nature and less serious than the human variety All cases of ascites in children were not necessarily tuberculous in nature. Some of those which recovered might be instances of a simple chronic peritonitis

Dr LEONARD G GUTHRIE read a paper on the medical treatment He thought that in the opinion of some surgeons the discussion of anything connected with tuberculous peritonitis except surgical interference would be mere waste of time. Dr Guthrie however, thought that it was probable that the surgeons might learn something from Ambroise Paré who during a campaign had ran short of boiling oil and could not sleep one night for thinking of the sad plight of the wounded in consequence. Much to his surprise, however, he found the following day that they were much better without it If cases of tuberculous peritonitis were watched instead of being operated upon with the majority it happened that they did well. The surgeons might say that the cases in which recovery took place were not tuberculous, but Dr Guthrie thought that it was a little hard that the physician should be right when he called the surgeon in and wrong when he did not. Possibly the letting out of fluid was beneficial, but Dr Guthrie considered that in acute cases, unless the fluid produced great distension and distress, it was inadvisable to interfere, for if the fluid was removed it would speedily reaccumulate. In more chronic cases, however, where the fluid showed no tendency to subside it should be withdrawn Tapping or aspiration was dangerous and a small incision followed by a blunt trocar should be used While, however, the value of laparotomy except in some cases where complications arose, was doubtful, the use of remedies such as mercury and arsenic was a matter of opinion. The treatment was mainly symptomatic with rest in bed, and after recovery hygienic. Some cases were greatly benefited by the fresh air treatment.

Mr W WATSON CHEYNE thought when he heard of the change of front of the physicians that they had discovered some new remedy, but he found that it was only that they had come to realise that tuberculous peritonitis was curable. For that discovery they had to thank the surgeons, since six years ago he had been unable to find any statistics bearing upon the prognosis. The discovery by the surgeons was no doubt the result of accidents made in cases where the diagnosis had been doubtful or mistaken, but the fact remained that the physicians were indebted to the surgeons for their knowledge on this point As to the comparison of statistics of cases medically and surgically treated Mr Cheyne believed that the worst cases were taken to the surgeon, so that no comparison could be made While he wished to keep an open mind on the subject he could not yet admit that laparotomy was of no value. Mr Cheyne admitted that it was difficult to understand how laparotomy could be beneficial, but it possibly altered the tension of the circulation and thus gave indirectly a stimulus to reparative changes.

Mr F C ABBOTT thought the cases particularly benefited by operation to be those which started in diseased Fallopian tubes or ovaries, and Dr R H. A. WHITELOCKE (Oxford) expressed similar views

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY

Exhibition of Specimens.—Prolapse of the Urethra

A MEETING of this society was held on Dec. 19th, 1902, Dr S BUCKLEY (Manchester), the President, being in the chair

Dr D LLOYD ROBERTS (Manchester) showed a specimen of a Papilliferous Cystadenoma removed from the Abdominal Wall 14 years after Ovariotomy The patient, who was a married woman, aged 48 years, a VII para, and whose last child had been born four years previously had noted a lump in the abdomen for about six months. It was steadily increasing The left ovary had been removed for cystic tumour 14 years previously The tumour was felt just to the left of the cicatrix left by the former operation. It was attached to the abdominal wall but was freely moveable otherwise. It felt hard but resonance was only slightly diminished over its surface. The abdomen was opened and about three pints of ascitic fluid escaped. The tumour was found to be attached to the cicatrix and was intimately connected with the parietal peritoneum. Some coils of intestine adhered to the under surface and required separation The cyst was carefully detached and removed. There was no pedicle. The right ovary was healthy and there was no trace of the left ovary which had been removed 14 years before. The patient recovered The specimen was described as a papilliferous cystadenoma of the subperitoneal tissues of the abdominal wall The structure closely resembling that commonly occurring in the ovary suggested that the growth was secondary to the ovarian tumour previously removed

The PRESIDENT showed a large Fibromyoma and Cystic Ovaries removed by abdominal section The operation was undertaken in consequence of the severe pain, especially on the left side, which had existed for two or three years There had recently been an increased menstrual flow but this increase had not been sufficient to interfere with nutrition. When the abdomen was opened a large fibroid was found attached by a short broad pedicle to the fundus uteri. The growth was removed by myomectomy as were also two smaller fibroids from the anterior surface of the uterus. The ovaries were found to be cystic and were of the size of large walnuts They were adherent and wedged between the tumour and the uterus, and after separation were removed together with the tubes It was probable that the severe pain had been chiefly due to the condition of the ovaries and to their compression by the growth The patient recovered well and is free from pain.

Dr W WALTER (Manchester) showed a Solid Ovarian Tumour removed from a patient, aged 58 years The swelling had been noticed about three years, but during the last 12 months it had increased more rapidly and the presence of ascites had become obvious There was no loss of flesh or cachexia, but the patient s three sisters had all suffered from abdominal tumours. The tumour had a short pedicle and was so closely adherent to the back of the uterus that the signs were those of a uterine tumour rather than of an ovarian tumour The ascitic fluid was reddish and amounted to about two pints The other ovary was cystic and contained a small fibroid nodule The microscopical sections showed the growth to be a simple fibroma with commencing myxomatous degeneration. The patient made a good recovery The difficulty of diagnosis and prognosis in solid ovarian tumours was discussed —Dr Walter also showed an ovarian cyst with a twisted pedicle

Dr H BRIGGS (Liverpool) showed - 1 A small Ovarian Cyst (2¼ inches by 4¼ inches) associated with metrostaxis and retro uterine hæmorrhage. 2 A Fundal Fibroid Polypus and Inverted Uterus. The uterus and growth had been successfully removed by vaginal hysterectomy The patient having passed the menopause no attempt was made to save the uterus. Reposition of the uterus after removal of the polypus would no doubt have been impossible 3. An early Cancer of the Cervix Uteri.

Dr ARNOLD W W LEA (Manchester) related a case of Acute Prolapse of the Urethra. Owing to the œdematous and strangulated condition of the prolapsed mass it was found necessary to resect this part of the urethral mucous membrane The result was completely satisfactory The cause of the condition was obscure There was a little cystitis, but this was probably not present before the attack. Masturbation was suspected

WEST LONDON MEDICO-CHIRURGICAL SOCIETY —A meeting of this society was held on Jan. 2nd Mr Rickard W Lloyd, the President, being in the chair —Dr Neville T Wood read a paper on the Treatment of Chronic Heart Weakness by Baths and Exercises in Family Practice. Chronic heart failure might, he said, be divided into four stages (1) a period when compensation was efficient, (2) a stage when the heart worked well under favourable conditions but failed under those of medium stress, (3) when the circulation was

Reviews and Notices of Books.

An Essay on Laughter its Forms, its Causes, its Development, and its Value By JAMES SULLY, M.A , LL.D London Longmans, Green, and Co. 1902. Pp. 441. Price 12*s* 6*d* net

PROFESSOR SULLY has produced a searching and interesting work upon a very inviting theme. It is not to be expected that a psychological essay should be anything but solid merely because it deals with a light subject—laughter Our lightest actions, our most trivial movements, our least serious ideas, become matters of solemn moment when they are regarded in the light of evolution of modes of expression or when from them it is attempted to deduce the foundations and the course of action and speech and thought in general. Nevertheless, in this essay on laughter, among much serious and perhaps at times laboured consideration of emotions and expressions themselves anything but serious, the author has managed to introduce an appropriate anecdote or two and a spice of the humorous which come as an unhoped for oasis of amusement in a psychological work dealing with laughter Professor Sully is a laughter lover This is as plainly shown in the way in which he seizes any opportunity of treating a subject with humour as it is actually demonstrated in his text Medical readers will have no difficulty in supporting his contentions as to the physical benefits derived from open hearty laughter They will also be interested in the associations that the author makes between the physical and the psychical conditions involved in laughing The question is treated from the evolutionary standpoint in this book and perhaps its most interesting passages are those relating to the laughter of children and of savages and to the questions of laughter or allied expressions in animals such as apes and dogs In the examination of laughter on a wider basis, the "choral laughter,' as Professor Sully calls it, many pregnant observations are made upon the social groups into which a civilised community becomes differentiated and, generally speaking, we find ourselves better pleased with the writer's manner and grasp of his subject when he is dealing with broad considerations such as these than when he is involved in a minute investigation of some individual mental attitude. We read with greater pleasure the explanation of culture groups in a community and the way in which laughter is evolved from among them than we did, for instance, the detailed examination of the "hat comedy"—the comedy wherein a father in his child's hat and a child in his father's hat are under comparison as laughter raisers.

LIBRARY TABLE.

Lectures on the Use of Massage and Early Passive Movements in Recent Fractures and other Common Surgical Injuries, the Treatment of Internal Derangement of the Knee joint, and the Management of Stiff Joints. By Sir W H. BENNETT, K.C V O , F R C S. Eng , Senior Surgeon to St. George s Hospital, Member of the Court of Examiners, Royal College of Surgeons of England, &c. Second edition, with 17 illustrations. London New York, and Bombay Longmans, Green, and Co 1902 Pp. 115. Price 6*s*.—The value of massage in the treatment of recent fractures was first pointed out by Lucas Championnière, but the practice received little support in this country until Sir William Bennett advocated its adoption There is no better account than that contained in this work of the method of carrying out the treatment of fractures by means of massage The massage is combined with early passive movement and with what is called "internal massage'—that is to say, the voluntary movement of the muscles which lie about the fractured bone. We commend the treatment to all those who have not tried it and we venture to say that they will be surprised at the early mobility obtained and the absence of adhesions Of course the method must be employed with care if the best results are to be secured. The volume also contains an interesting lecture on Internal Derangement of the Knee-joint with its treatment and a lecture on the Treatment of Stiff Joints by Forcible Manipulation , and the author gives a skiagram of a knee in which forcible flexion produced fracture close to the joint. This chapter is certainly of value and affords important information on a subject which is but scantily dealt with in the text-books.

Operations-Vademecum für den Praktischen Arzt (*A Vademecum for Operations.*) Von Dr EDMUND LESER, Professor an der Universität Halle-a S , Mitglied der Kaiserlichen Leopoldino-Carolinischen Deutschen Akademie der Naturforscher Mit 84 zum Theil farbigen Abbildungen. Zweite vermehrte und verbesserte Auflage. Berlin S Karger 1902. Pp 186. Price 5 marks —This little volume is intended to assist those surgeons to perform operations who may suddenly be called upon and yet have had little or no previous experience in operating In the case of each operation there is first a list of the instruments required and then a somewhat brief account of the procedure. In many cases very useful practical hints are given Many diagrams are provided and some of them are useful. We may specially mention those illustrating the operation for hare lip and other plastic operations on the face In these the incisions required are marked in red, thus showing very clearly what has to be done. Photography has been largely used in the preparation of the illustrations and generally with success, but some are less happy , for instance, Fig 6 is intended to show the operation of ligature of the brachial artery at the bend of the elbow , this figure is useless, as really nothing can be seen

The Treatment of Fractures By CHARLES LOCKE SCUDDER, M.D , Assistant in Clinical and Operative Surgery, Harvard University Medical School, Surgeon to the Out-patient Department, Massachusetts General Hospital Third edition, thoroughly revised, with 645 Illustrations. London and Philadelphia W B Saunders and Co 1902. Pp 485 Price 19*s* net.—In THE LANCET of June 22nd, 1901, p. 1766, we noticed at some length the second edition of this work and we then drew attention to the lavish supply of illustrations. In the present issue the illustrations have been increased by 45, while the pages only exceed those in the previous edition by 25. A chapter on Gunshot Fractures of the Long Bones has been added and the author has incorporated in his description many facts and illustrations from Mr Makins's ' Surgical Experiences in South Africa." This is a valuable account of the effects of the small bore bullet. Thus the additions to the volume, though not very numerous, are of some importance and the work is certainly a clear and trustworthy guide to the treatment of fractures

Lehrbuch der Hautkrankheiten. (*A Text-book of the Diseases of the Skin.*) Von Professor EDUARD LANG, K.K. Primararzt im allgemeinen Krankenhause in Wien, Mitglied der Kaiserlichen Leopoldinisch Carolinischen Akademie, &c. Mit 87 Abbildungen im Text Wiesbaden Verlag von J F Bergmann. Obtainable from F Bauermeister, Glasgow 1902. Pp 655. Price M. 14 60 or 14*s* 9*d* —The name of Professor Lang is well known in this country for valuable dermatological work that he has done and therefore a systematic treatise on the diseases of the skin will be sure to meet with appreciation here This work contains a fairly full account of dermatology and appears from its arrangement and size to be very suitable for the use of students and medical practitioners who quarters, well and made an uneventful recovery Her urine, drawn off every three hours, was blood stained for three or four days, as was the gauze from the cavity in the broad ligaments, but she was well enough five weeks after the operation to be sent to a convalescent home.—Dr Bedford Fenwick pointed out the valuable information to be gained by passing a vesical sound when operating on large tumours and for large cavities in the broad ligaments he recommended complete closure above and drainage through the vagina.—Dr Herbert Snow said that the microscopic section proved that the tumour was sarcomatous, but the duration for ten years suggested that it was the result of degeneration of a fibroid.—Mr F Bowreman Jessett had found a catgut suture of the mucous membrane with Halsted's suture of the peritoneum an efficient way of closing wounds of the bladder, for which he did not think more than two layers were required, but he would have preferred to introduce in this case, as he was in the habit of doing in all his vaginal hysterectomies, a self retaining catheter, to spare the patient the annoyance of the repeated passage of an instrument.—Dr Macnaughton Jones did not consider that vaginal drainage of such a cavity as the one described was desirable if complete hæmostasis could be secured —Dr Duncan replied.—The President delivered his valedictory address Specialism, he pointed out, not only had great advantages, but was now absolutely necessary on account of the vastness of the field opened to the medical profession by the increase in scientific knowledge due to new and improved methods of research. Whatever the future of gynæcology might be it had made more substantial progress than any other branch of surgery He could understand the position of those who held that as absolute diagnosis was often impossible until the abdomen had been opened the operating gynæcologist must be a skilled abdominal surgeon, and that if a general surgeon was to do hysterectomy a gynæcologist might perform gastrotomy But the difficulty was where the line was to be drawn if gynæcology was to remain a specialty The tendency at present was to ignore the medical element in gynæcology, but even on its surgical side its proper field was the genito-urinary tract. In Edinburgh he and his colleagues professed obstetrics and the diseases of women, and he held that to be the reasonable position for gynæcologists to adopt.

Aberdeen University Medical Society —At a meeting of this society held on Jan 9th, Professor J T Cash presiding, a very interesting and lucid paper on Anæsthesia, Past and Present, was given by Professor J A. MacWilliam. Sir Humphry Davy advised the use of nitrous oxide for small cases where there was not too much bleeding without giving any reason for the reservation Chloroform began by paralysing the higher centres and worked downwards, but certain centres were exempt—vaso motor, respiratory, &c —and on this fact depended the possibility of anæsthesia. Localised anæsthesia of blood going from the lungs to the heart was caused say, by the patient taking a few rapid breaths, so that a quantity of chloroform, harmless when uniformly spread over the circulation, might, when localised prove fatal. The best way of administering chloroform was to put the patient partially under, then to let him come out, and then to place him under it again. The administrator should always allow a good deal of air to be inhaled at the same time Idiosyncrasy affected its influence—cats, which closely resembled the human subject in many ways could not in some cases be killed by chloroform, though of course, they were deeply anæsthetised They had to consider more than one symptom in cases of collapse. If respiration failed artificial respiration was enough If the heart was paralysed squeezing the heart rhythmically with the hand was a powerful remedy in the case of a cat, in one human subject recently the heart was successfully squeezed through the diaphragm —Dr J Scott Riddell said that severe bleeding accompanied throat operations under nitrous oxide anæsthesia Out of 10,000 chloroform operations he had seen, only five deaths had occurred He strongly advocated the special course on anæsthesia which was to be given at the Infirmary

Glasgow Pathological and Clinical Society —A meeting of this society was held on Jan. 12th, the President, Dr A. E Maylard, being in the chair Dr Henry Rutherfurd showed (1) a child operated on for Intussusception at the age of three months, and (2) a child showing Scars of Intra uterine Small pox and Deformities probably due to the same cause, and read notes of the cases —Dr John H. Treacher gave a lantern and microscopical demonstration of Chorionepithelioma (deciduoma malignum of authors) and of Chorionepitheliomatous and Hydatidiform Mole like Structures in Teratomata of the Testis The latter part was from preparations the gift of Dr Schlagenhaufer of Vienna, Dr Schmorl of Dresden, and Professor Marchand of Leipsic. Dr Treacher also gave a short account of the opinions held as to these tumours —Dr J Kerr Love and Dr J W Leitch showed a specimen of Aneurysm of the Aorta in which death occurred from rupture of the heart and read notes of the case —Dr J K Kelly read notes and showed a specimen and microscopic sections of Sarcomatous Disease of the Uterus and Right Ovary, with Adeno-cystoma of the Left Ovary, removed from a patient, aged 66 years —The following exhibits were on view during the meeting—by Dr R S Thomson and Dr Robert Fullarton, (1) Water colour drawings illustrative of the Prodromal Rashes of Variola, &c, and (2) photographs illustrating various phases of the Variolar Eruption, by Dr John Brownlee, a microscopical demonstration illustrating certain features of the Variolar Eruption, and by Dr T K Monro, a Water colour Drawing by Dr A. J Ballantyne representing Severe Scrofuloderma.

Edinburgh Royal Medical Society —A meeting of this society was held on Jan 9th, Dr S A K Wilson being in the chair —A paper on Ectopic Gestation was read by Dr M Holmes. The paper was illustrated by four cases which had been treated lately in the Edinburgh Royal Infirmary He emphasised strongly the value of getting a correct history in diagnosing such cases In two of the cases the patients were not operated on and they had made a good recovery —Dr A. H Firth read notes of the following cases 1 A case pointing to Circulatory Embarrassment. After being in hospital some time the patient died suddenly A section of the liver and also a section of the lung were exhibited The former showed marked chronic venous congestion and the latter silicosis 2 A case with symptoms pointing to Lung Trouble. The post mortem examination demonstrated a sacculated aneurysm of the arch of the aorta.—A communication on Intestinal Obstruction in the Child by Dr Hey was read in his absence by Mr Nutt.

Æsculapian Society —A meeting of this society was held on Jan 9th, Dr Thomas G Stevens, the President, being in the chair —The President read a paper on Uterine Prolapse He said that the causes of prolapsus lay in the weakening of the pelvic floor through laceration of the levatores ani and undue stretching of the ligaments of the uterus during confinement. At the labour's completion or within the next three months the surgeon could cure the prolapsus but later than this time cure could only be expected by a radical operation, such as amputation of the cervix uteri, curetting the uterus and repairing the perineum When prolapse of the uterus occurred in virgins it was usually associated with anæmia and was due to some intra abdominal extra pressure. He advocated in the early cases repair of the perineum, the use of a vaginal glycerine plug to excite vaginal secretion, to induce uterine involution and to stimulate the levatores ani, rest in bed, and the application of a firm perineal pad

Birkenhead Medical Society —A meeting of this society was held on Jan 9th, Mr G S Stansfield (in the absence of the President) being in the chair —Dr J Herbert Dixon drew attention to the working of the Vaccination Act, in view of the probability of its being modified next year He proposed the following motions, which were seconded by Dr J Lambert and unanimously agreed to —

1 That the post of public vaccinator should be abolished and that every registered medical practitioner should be paid by the constituted authority for vaccinations performed

2. That the names of all children for whom at the age of four months the necessary certificate is not forthcoming should be handed by the vaccination officer to the parish medical officer for the district in which such children are resident who should vaccinate them and be paid at the same rate as other practitioners

3. That lymph should be supplied by the Government

4 That the conscientious objector's clause should be abolished.

Bristol Medical Charities —The employés of Messrs. W and H. Wills contributed £457 in 1902 to the Bristol medical charities. The employés of Messrs. E. and A Robinson contributed £285 for the same object.

manufactured and supplied by Mr F Davidson, optician, 140, Great Portland street, W, to whom I am much indebted for the skill and care with which my ideas have been carried out. The ophthalmoscopic drawings were all executed by Mrs. Davidson whose artistic talents are well displayed therein while to Messrs. Bale, Sons, and Danielsson much credit is due for their excellent lithographic reproduction of the drawings The price of the model is very moderate

H PERCY DUNN, F R C S Eng
Ophthalmic Surgeon to the West London Hospital Lecturer on Ophthalmology at the West London Post Graduate College
Wimpole-street, W

MEDICINE AND THE LAW

Indecent Literature and the Law

SEVERAL prosecutions have taken place during the opening days of 1903, both in the City of London and elsewhere in the metropolitan district, in which the defendants have been street hawkers who have been fined for selling indecent literature. This might be taken to indicate an awakening of zeal on the part of the authorities on behalf of the public morals, but a perusal of the work objected to hardly bears this out. It consists of a skit upon the new Licensing Act apparently written by a somewhat illiterate person, and although it is unquestionably vulgar without being in the least degree amusing it requires a stretch of the imagination to describe it as indecent. Indeed, the Lord Mayor and another magistrate appear to have felt obliged to lay stress on the fact of the sheet objected to being headed with the Royal arms, the use of which may be illegal but can hardly be indecent within the police court meaning of the term If the police authorities desire to punish poor men for offences such as these they might well turn their attention to richer ones first They might, for example, examine the advertisements in cheap periodicals of quack nostrums for the treatment of nervous debility, of lost virility, and venereal diseases which would be indecent by statute if affixed to the walls of a public latrine and are not, so far as we are aware, rendered more seemly by appearing in the public press The advertisements of quack abortionists were long tolerated without complaint and have only disappeared because a few of the advertisers themselves have been successfully proceeded against. Even this class of obnoxious, and in our view indecent advertisement has not entirely vanished and "female remedies" are still occasionally offered with impunity If, however, they have doubts on the subject of the advertisements themselves the police authorities, at the cost of a few shillings spent in correspondence with the advertisers, might possess themselves of a mass of indecent literature far more likely to corrupt and to ruin ignorant young men and women than the silly broadsheet to which they called unnecessary attention in the cases to which reference has been made above.

The Licensing Act, 1902

There can be no doubt that the opening sections of the new Licensing Act which refer to drunkenness are being eagerly made use of and that as their provisions become more widely known by means of the police reports frequent recourse will be had to them throughout the country They concern medical practitioners because they increase the number of offences in which drunkenness is an essential feature and in the trial of which the fact of drunkenness may be disputed and may have to be proved or disproved by medical evidence. Under the new Act a person found drunk and apparently incapable of taking care of himself in a highway or public place may now be apprehended and dealt with according to law Before the present year such a person was usually taken to the police station in order to secure his own safety but on the following day he could not technically be taken before the magistrate without first being released and summoned. Persons found drunk in public when in charge of children under seven years of age may now be severely punished and it is not necessary that these should be apparently incapable of taking care of themselves. A married man or woman can obtain from a court of summary jurisdiction an order of separation from a wife or husband by proving that she or he is a habitual drunkard. In cases in which an order of detention under the Inebriates Act, 1898, might be made the magistrate must, whether he makes such an order or not, cause a notice to be sent to the police authority which will have as its result that the person convicted may be punished for obtaining liquor on licensed premises during the next three years and that any person knowingly serving him with liquor may be punished also The habitual drunkard for the purpose of an order of separation from a wife or husband is defined by the Habitual Drunkards Act of 1879 as "a person who not being amenable to any jurisdiction in lunacy is notwithstanding by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself or herself or to others, or incapable of managing himself or herself, and his or her affairs" It is as well that attention should be called to this because in one or two instances magistrates before whom separation orders have been sought seem to have been under the impression that the "habitual drunkenness" could only be established by proof of convictions for offences connected with drink. It is easy to see that although medical evidence is not likely to be required very often in the case of the poorest class whose lives are patent to their neighbours and who are less eager to disguise their failings, with regard to those occupying a better position the case is different and medical evidence may be of considerable importance The instances also that have occurred in the past of the police and public mistaking sudden illness for drunkenness are not likely to become less frequent. It is to be observed that the new Act does not apply to Scotland or Ireland

Who is to Blame?

It has been stated, with reference to the cases of typhoid fever at Winchester believed to be caused by eating oysters that the owner of the Emsworth beds, from which the oysters in question apparently came, is threatening an action against the local authority and that he will claim heavy damages from them for the injury done to his trade through the alleged contamination of the oyster beds with sewage matter It was said at a meeting of the urban district council concerned that the conditions complained of were due to the bringing of the oysters to the sewage, rather than to the bringing of the sewage to the oysters, and it was resolved to defend any action which might be brought. Apart from the questions immediately concerning the parties in this instance the trial of such an action should be watched with attention by those concerned with the public health, as whatever its result may be it can hardly fail to define in a manner highly to be desired the rights and liabilities of local authorities and of the dwellers in their districts with reference to the disposal of sewage matter, both generally and in respect of the discharge of sewage into tidal and other waters

---

WINSLEY SANATORIUM —The Swindon town council has decided to contribute £500 towards the cost of the erection of the sanatorium for consumption at Winsley and to contribute £130 annually towards the maintenance of the institution, provided that two beds are reserved exclusively for cases from Swindon

ROYAL INSTITUTION —The course of six Christmas lectures at the Royal Institution was delivered by Professor H S Hele Shaw, professor of engineering in University College Liverpool, on Dec 27th and 30th, 1902 and Jan 1st, 3rd, 6th, and 8th, 1903 These lectures, which are adapted to a juvenile auditory, dealt with Locomotion (1) on the earth, (2) through the water, and (3) in the air The first lecture was taken up with preliminary considerations relating chiefly to wheels and rails The second described the various kinds of motor car for ordinary roads driven either by petrol, steam or electricity The third and fourth lectures dealt with vehicles travelling on rails—namely, ordinary railway trains with steam locomotives or electrical locomotives and electrical tramcars. No electrical railway existed 25 years ago the first one was in Berlin and commenced working in 1879, the first successful one in the United Kingdom was at Portrush in Ireland, the dynamos generating the electricity being driven by water power A description was also given of the so-called mono rail, which really consists of five rails—one for supporting the carriages and a pair of rails on each side for steadying them. The fifth and sixth lectures were devoted to various types of steamships, balloons, and flying machines.

wish to have a general knowledge of the subject and a convenient work of reference For such purposes the descriptions of the diseases and the sections on treatment are amply sufficient, but the absence of references will detract from its value for dermatologists, though indeed it makes no claim to be an exhaustive treatise. There are 87 illustrations , some of these represent histological details, but the majority are reproductions of photographs of patients, and so far as skin diseases can be shown in black and white they are successful. One of the illustrations represents a very severe case of keloid resulting from a burn with sulphuric acid and another shows the same case after excision, some of the wounds so formed being stitched up and others covered with Theirsch grafts. This case is of interest, as many surgeons hold that excision is useless in keloid recurrence always taking place Another excellent illustration is one showing a case of psoriasis with conical scabs, "psoriasis ostreacea."

The Hair and its Diseases, including Ringworm, Greyness, and Baldness an Introductory Handbook. By DAVID WALSH, M D Edin., Physician to the Western Skin Hospital (Medical Monograph Series, No 6) London Baillière, Tindall, and Cox. 1902 Pp 96 Price 2*s* 6*d* net —There is much that is good in this little book, for it sets forth clearly the manifold microbic dangers to which the scalp and hair are liable and gives useful directions for avoiding the spread of infection, but the general plan of the book and many of the phrases and expressions used seem to indicate that it is intended for the perusal of the layman rather than of the medical man As ' unkempt" simply means uncombed it is somewhat curious to read that "were it not for daily brushing the head would soon become unkempt and full of dust"

Prize Essay on the Erection of a Sanatorium for the Treatment of Tuberculosis in England By ARTHUR LATHAM M D London Baillière, Tindall, and Cox 1903. Price 5*s* —The essay which gained the first prize among the competing essays for a scheme for the erection of the King's Sanatorium has now been published in separate form by Messrs Baillière, Tindall, and Cox. The essay as published in a volume is identical save for the addition of a bibliography, with the essay published in THE LANCET of Jan 3rd The bibliography, which is a very complete one, was added with the idea that it might be of some service to His Majesty's Advisory Committee and consists of references to books and articles on sanatoriums and on the sanatorium method of treatment, showing the author's intimate and wide acquaintance with the subject With the larger type, the side headings, and the varieties in printing which the volume form permits of, Dr Latham's essay makes a very attractive as well as a very useful little book, while the rapid and excellent production is a matter upon which the publishers must be congratulated The sanatorium treatment of pulmonary tuberculosis is now the recognised method of dealing with many classes of cases and medical men and public authorities are glad, as we know of an opportunity of learning what is at the present time considered to be the most effective form of building

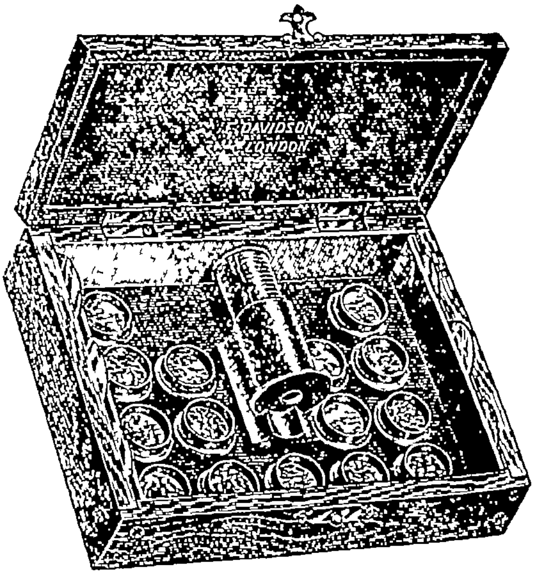
JOURNALS AND MAGAZINES

Practitioner —The January number of this periodical introduces a new editor—Dr W Cecil Bosanquet—and a new external appearance. We cordially welcome both. The altered form of the journal is certainly to its advantage and it is now a well printed substantial looking production with the list of contents readily displayed. As to the contents of this particular number there is no marked change to remark from the usually excellent class of contribution that the *Practitioner* has led us to expect, unless it be in the editorial notes. These are of a character purely professional rather than professionally political as they were wont to be

New Inventions.

AN IMPROVED MODEL EYE.

THE next best thing to practising retinoscopy and the use of the ophthalmoscope with the human eye is to employ an appliance which almost answers the same purpose. Believing, however, that a model eye completely fulfilling these requirements has so far not been available for practitioners and students I proceeded some time ago to devote attention to the subject and I now venture to think that the result described below will be helpful in supplying the need indicated The model itself is an improvement upon a design which has for some years been known in America. It consists of two brass (blackened) cylinders one of which is fixed on a stand, the other being moveable, sliding backwards and forwards inside the former On the moveable cylinder is a printed graduated scale by which a maximum of myopia of 6 D and of hypermetropia of 6 D can be measured At one end of the fixed cylinder is a lens of two-inch focus, thus enabling the observer, by altering the position of the moveable cylinder, to produce various degrees of ametropia The beginner, for example, might make the model eye myopic to 4 D and proceed with the lenses taken from an ordinary trial case to estimate the defect, having arrived at the correction he can then ascertain by looking at the graduated scale whether his result corresponds therewith Furthermore, different lenses are provided with the model, by which various degrees of astigmatism can be created by merely inserting one or other of the lenses in front of the lens in the fixed cylinder In addition a diaphragm is supplied to be placed in the slot in front of the two inch lens for the purpose of representing the pupil in an undilated state. For the study of changes in the fundus 17 metal discs are provided so made as to cover the outer end of the moveable cylinder, each containing an ophthalmoscopic drawing On the reverse of these discs a number is placed which corresponds with a number on a printed list fixed inside the lid of the box, the idea being that the student should first examine the drawing with the ophthalmoscope in the ordinary way and make a diagnosis of the condition of the fundus depicted before referring to the list.



The following is the list of drawings in question (1) optic neuritis , (2) posterior staphyloma , (3) coloboma of the choroid , (4) normal eye , (5) retinitis pigmentosa , (6) opaque nerve fibres , (7) syphilitic neuro-retinitis , (8) detachment of the retina , (9) sarcoma of the choroid , (10) advanced chronic glaucoma , (11) sub-hyaloid hæmorrhage , (12) albuminuric retinitis , (13) post-neuritic atrophy , (14) disseminated choroiditis , (15) embolism of the central artery of the retina , (16) rupture of the choroid , and (17) primary atrophy of the optic nerve. The model is it may fairly ask the public to find the money for the structure. For the proposed course there is this to be said. The governors of the hospital are mostly City men As the hospital is clearly wanted in the City—of that there is no doubt—why should not the Lord Mayor of the City ask the citizens for the money to keep the institution in their midst at the highest pitch of efficacy? Against the appeal by St Bartholomew's to the charitable public it must be urged that many other hospitals, notably the London Hospital and Guy's Hospital, are in great financial straits. The endowment of the former is inconsiderable and the income of the latter has dwindled terribly of late years. An appeal to the public from St. Bartholomew's Hospital may undoubtedly tend to divert funds from the London Hospital and Guy's Hospital, neither of which institutions has any other way of obtaining money save by appeals to charity In these circumstances, while we recognise that St. Bartholomew's Hospital requires the immediate expenditure of a large sum of money upon its fabric to render it a suitable place for the treatment of the sick, we deeply deplore that the governors can make no effort to cope with the financial position out of the great resources of their institution It seems to us better for the public that St. Bartholomew's should temporarily bear the burden of a debt to the bank than that supplies which are the very life blood of other charities should be jeopardised.

◆

Infective Arthritis

THE Bradshaw Lecture at the Royal College of Surgeons of England which was published in our columns on Dec 16th, 1902 (p 1603), proved to be a particularly valuable contribution to medical knowledge Mr HOWARD MARSH took for his subject certain cases of affections of the joints which do not fall readily into any of the recognised categories of articular disease In a damp but temperate climate like that of England rheumatism in one or other of its manifestations is an exceedingly common disease and therefore if any obscure affection of the joints is met with there is always a very great probability that it will be classified as "rheumatic," just as in countries where malaria is rife any rise of temperature or disturbance of doubtful origin is put down to malaria. So it has happened that the term "rheumatism" has become extremely wide, as it is applied to many conditions which have no other connexion with true acute rheumatism than that they affect joints

Mr MARSH very happily started with a comparison between the peritoneum and the synovial membranes. It is not so very long ago that peritonitis was considered to be often idiopathic" but now it is recognised that no such condition exists and that peritonitis is microbic in origin. Histologically there is the closest resemblance between the peritoneum and the lining membrane of joints, and pathologically the likeness between these two structures is also very great, and therefore *a priori* we should look for a microbic origin for synovitis and arthritis. In the first part of his lecture Mr MARSH pointed out that in the great majority of the specific diseases the joints are liable to be infected. This is fully acknowledged with regard to tuberculosis and syphilis and these diseases were therefore not considered further, and ordinary septicæmic infections and gonococcal arthritis were also put aside as too well known to need discussion The lecturer then discussed seriatim various morbid conditions which are associated with an infective arthritis He showed that the starting point of our present view was the discovery by WEICHSELBAUM in 1888 that the pneumococcus has the power of producing an acute inflammation of the joints, and a paper by Dr E J CAVE, published in THE LANCET of Jan. 12th, 1901, p 82, advanced our knowledge greatly, in this article it was pointed out that pneumococcal arthritis generally sets in only a few days after the onset of an acute pneumonia, though occasionally it may precede the pulmonary affection, and in a few cases it has occurred independently of any pneumonia. In a very large proportion of the cases the inflammation went on to suppuration and nearly three fourths terminated fatally, but this very high mortality is not to be ascribed to the affection of the joints only for the pneumonia and other inflammations which are present, such as endocarditis and meningitis, are largely responsible for these unfavourable results Of all the forms of infective arthritis there is probably none worse than that due to the pneumococcus, for it is essentially a septic infection In typhoid fever, too, affections of the joints are not uncommon. Some of these are examples of ordinary septic arthritis, the streptococci or staphylococci having been absorbed from the surface of the ulcers in the ileum or from bedsores or boils. There is a second form of articular affection in typhoid fever which is apparently due to the presence and direct action of the typhoid bacillus. In these cases suppuration is rare, complete recovery sometimes occurring, while in others fibrous ankylosis results. There is yet a third form of articular affection in enteric fever, it arises early, lasts only a few days, and then disappears, leaving no ill effects behind. These cases have been called examples of "rheumatic typhoid arthritis," but the name is confusing, for no one will maintain that they have anything to do with true rheumatism. It is not improbable that they are the result of irritation by toxins and that the typhoid bacillus is not present in the joints affected. Accompanying scarlet fever are two forms of articular disease, one of these is suppurative and is probably merely a part of a secondary sepsis but the other is early in its appearance, is not severe in character, and usually soon subsides. It has been looked upon as a true rheumatism but far more likely it is a veritable scarlatinal affection of the joints. Influenza, too, seems occasionally to be complicated by an affection of the joints which goes on to form a stiff joint and Mr MARSH related two instances of this condition which came under his own observation. When we consider how very common a disease influenza has been of recent years and still is this complication must be obviously very rare. Erysipelas and glanders may also be added to the list of diseases which are liable to be accompanied by an affection of the joints.

So far only articular complications of general diseases have been referred to, but there are certain unclassified cases of infective arthritis. Mr MARSH quoted two cases of bronchiectasis in which several joints were affected, and in one of these the condition of the joints varied with the bronchiectasis, when the sputum was small in

THE LANCET.

LONDON SATURDAY, JANUARY 17, 1903

St Bartholomew's Hospital

CRITICISM of rather lavish kind has been expended upon the affairs of St Bartholomew's Hospital lately in the columns of more than one newspaper, and to a large extent the articles which we have read have been the easy product of the versatile journalist, in that a broad flow of exaggerated notions has proceeded from a minute source of imperfect knowledge Such articles need not seriously detain anyone truly interested, and is there any medical man who can fail to be interested in the present position and the future welfare of the oldest and one of the greatest of London hospitals? All medical men know the good work that St. Bartholomew's Hospital, the hospital of ABERNETHY and PAGET, has done, and all will be concerned to learn that so venerable and dignified an institution is, despite its great possessions, about to make an appeal to the public for assistance Whether this appeal is justifiable has exercised the minds of many during the last week, and the question is a very difficult one to answer Some writers have been glib with regard to the iniquity of extending hospital accommodation upon land so valuable as that in the heart of the City and with respect to the advantages of removing a City hospital to a site more remote from the centre of London. Unfortunately, their rhetoric shows but too plainly a complete ignorance of the actual work carried on at such a hospital as St. Bartholomew's and only the faintest suspicion of the immense difficulties involved in any considerable change of position for such an institution. Two articles on the position of St. Bartholomew's Hospital which appeared in the *Times* of Jan 7th and 8th, are, however, well informed, and these, together with a consequent letter from Sir TREVOR LAWRENCE, the treasurer of the hospital, give a clear and judicious statement of the circumstances which have led to so much rambling discussion.

In the first place even the staunchest supporter of St. Bartholomew's Hospital will grant what has been already freely admitted by Mr ANTHONY A. BOWLBY and Sir THOMAS SMITH before the House of Lords committee—that there is much overcrowding in many departments at the hospital. The buildings, though finely designed and executed are excessively old for a hospital and incapable of rising to the best modern requirements of ventilation and sanitation. It is, indeed, because such considerations as these are fully realised by the governors of the hospital that they have gone to the length of expending nearly a quarter of a million of money upon acquiring additional space contiguous to the present hospital. That this sum has been largely provided from the savings of the hospital itself reflects credit upon the administration of the hospital, and is to some extent a justification of an appeal to public charity for power to carry out to the full the proposed additions and improvements. The public may always with propriety be asked to help those who help themselves If, however, St. Bartholomew's is justified in appealing to the public for large sums of money, the public in turn are equally justified in demanding that for these sums the greatest possible amount of benefit shall accrue. Will that be the case if these sums are expended in maintaining extensions and improvements upon land of almost incomparable value? Might not much more be done, and even better done, upon a site of less extravagant pretensions? Might not a still larger number of patients be as conveniently provided with hospital attention in a less central position? Two reasons for maintaining the hospital in its present position at once suggest themselves. The first is one that is quite obvious, though it has been ignored almost entirely by the critics of St Bartholomew's Hospital. There is a very large number of emergency cases, both surgical and medical, occurring daily within the City of London and requiring hospital treatment The public has the vaguest notions of what is meant by a day's work at St. Bartholomew's or any other large London hospital Half a dozen fractures a bad burn, two "run-over cases," and a "fall from a ladder" would make no extraordinary history of a morning's casualties received into the accident wards of St. Bartholomew's Hospital. Similarly there are numerous medical emergencies which daily require prompt attention in the City and there can be no question that considerable hospital accommodation is absolutely necessary within the City precincts Again, it must be remembered that St Bartholomew's Hospital serves the greater part of northern London It is the only large hospital for such populous districts as Highbury, Islington, and Clerkenwell, while it is a very accessible institution, having stations of the Metropolitan Railway, of the Central London Railway, and of two or three other railways at its gates. No new site is likely to be as convenient for either the patients or the medical staff as the present site is, and these are matters of prime importance which in all discussions that have come under our eye have been completely ignored. The second reason against a removal of the hospital is based upon what may be termed sentimental grounds. We may dismiss this reason more briefly than it deserves by saying that sentiment where it concerns the traditions of a great medical school as well as a great hospital is something more than an idle abstraction It plays an actual part in the production of enthusiastic and capable medical men

But while we are of opinion that St. Bartholomew's Hospital should remain, at any rate for the present, upon its historic site we are quite alive to the difficulties of the situation.[1] The hospital requires, to bring it up to modern standards of what a first-class hospital should be, a new isolation block, new operating theatres, new surgical out patients' rooms, new quarters for the resident staff and the nurses, new clinical laboratories, and a new mortuary It has acquired at an immense cost the site whereon to erect these necessary innovations, but, wealthy as it is, it considers that members of the Parliamentary bar and of most of the est known of water engineers. If the Water Board s to make anything of a fight on behalf of the eople whose interests are intrusted to it its policy must be directed with ability and with a strict regard to usiness principles. It will be well, therefore, if the members of the Board are men of knowledge and of nderstanding rather than men who darken counsel with plethora of verbiage. It is a wise provision of the ct that the electing authorities are not restricted in the hoice of their representatives It has been suggested by ir WILLIAM J COLLINS that the London County Council hould not elect members to the Water Board because it has ot exclusive charge of the whole enterprise. It is hardly be supposed that the Council will follow this advice which oes not appeal to us as practical. In the case of the etropolitan boroughs it may well be that gentlemen who ould firmly decline civic honours would in many cases e willing to place their special knowledge at the disposal f their fellow-citizens by service on the Water Board If ne or two distinguished engineers could be prevailed upon to ke this course the Board would be greatly strengthened.

---

[1] We recommend all our readers to refer to a letter published in our columns on April 5th, 1902, p. 990 from the pen of Mr Peyton T B Beale This communication discusses the growing difficulties of the London hospitals in a very interesting manner

It was suggested in the House of Commons by Mr ONG that Lord LLANDAFF might be invited to become member of the Board. No one in either House has a nowledge of the London water supply comparable in any gree to that which Lord LLANDAFF acquired whilst he esided over the Royal Commission which is associated ith his name and every one of the meetings of which he tended. The Metropolis Water Act is, however, a very ifferent measure to the one which he indicated and the ork done by Lord LLANDAFF has never been properly ppreciated—he has been abused by a certain section of e press and damned with the faint praise of his colleagues. e may well think that he has already spent enough time nd trouble over the London water question. There is, owever, one office which he could well hold, that of chair an of the Board The Board has the privilege of electing chairman from outside its own members, and if Lord LANDAFF at the unanimous invitation of the Board should onsent to fill that post we should consider the circumstance t happy augury

Annotations.

"Ne quid nimis."

SELF-PERFORMED OPERATIONS

IN THE LANCET of Dec. 20th, 1902, p 1716, we reprinted om THE LANCET of Dec 18th, 1824, an account of a litho omy performed by a French army surgeon on himself, the peration was a success and the surgeon patient completely covered On the perusal of such an account a feeling of oubt as to its truth might naturally arise, but there are ufficient cases on record to make it certain that such opera ons as this have been performed—nay, that even more evere operations have been carried to a successful termina ion by patients. In considering the reports of such cases e must put into an entirely separate category all those utilations which have been performed by persons of un ound mind, they are very numerous and of great interest, ut they must not be confused with instances of self perations for the treatment of a definite condition. In the case quoted from THE LANCET of 1824 the operator was a surgeon and therefore we need not feel so much surprise that the operation was a success as if he had not been acquainted with the subject, though our amazement at his endurance and perseverance is in no wise lessened. Gould and Pyle in their work on the "Curiosities of Medicine" mention that a Dutch blacksmith and a German cooper performed lithotomy on themselves In another case what may be called lithotrity was carried out on himself by a draper From the age of 17 years he had had a perineal fistula as the result of a fall Later he suffered from symptoms of a vesical calculus and he introduced a chisel through the fistula and chipped off pieces of the stone, this was continued and eventually the remainder of the stone came away, in all it weighed over 14 ounces He recovered and survived the operation 11 years. A somewhat similar case is that of General Martine who founded the Martinière Colleges of Calcutta and Lucknow He suffered greatly from stone and determined to rid himself of it. In order to do this he prepared a piece of wire and by filing roughened one end, converting it into a file. The wire was then introduced into the bladder and brought into contact with the stone, against which it was rubbed until the pain compelled him to desist, some débris came away This procedure was repeated until after 12 months' work all the stone was removed Dr James Murphy has recorded a case in which a man suffering from strangulated inguinal hernia incised the swelling with a razor, cutting off two large masses of omentum and almost completely severing the spermatic cord. It is somewhat doubtful if this case falls within the scope of the subject under consideration, as though the intention was curative the operation was not a success and in all probability the patient was insane at the time The most impressive cases of self operation are those in which Cæsarean section has been performed. These are numerous and, curiously, no small number has been recorded in coloured women Many of the cases have been successful, the uterus contracting firmly and very little blood being lost. A razor has generally been the instrument, though in one case a broken butcher's knife was used. Occasionally the child has been wounded, sometimes fatally The incision is most often made to the right of the middle line, but in some cases it has been median. Prolapse of intestine has occurred in some instances. In one case a neighbour sewed up the abdominal wound and recovery followed. The most remarkable case was reported in *La Gazzetta degli Ospitali* in May, 1886, and a *resumé* was published in THE LANCET of May 8th. A peasant woman, aged 23 years, who was pregnant opened the abdomen with a kitchen knife by an incision on the right side and as she found it impossible to remove the child its head and one arm were removed. The uterus having been emptied she tied a broad bandage tightly round the body, did some household work, then went on a cart to visit her sister, walked about for five hours, and then fainted. On examination an extensive prolapse of intestine was found to have occurred through the wound. This was cleansed and returned and the wound was sutured. Complete recovery followed.

SHELL-FISH AND TYPHOID FEVER

THERE is no doubt that the recent outbreak of typhoid fever at Portsmouth Southampton, and Winchester, caused by oysters, urgently calls for fresh legislation which shall apply to shell fish of all kinds. According to the report of the medical officer of health of Portsmouth, Dr A. Mearns Fraser, it would appear that in the present state of the law the sanitary authority is almost helpless There is legally no power vested in a sanitary authority by which the sale of oysters may be prevented because they may amount and only slightly fœtid the affection of the joints was less severe, but as the sputum increased in quantity and fœtor so the articular condition grew worse. In this case we cannot avoid the conclusion that the condition of the joints was dependent on the absorption of a toxin from the dilated bronchi Two very instructive cases were under the care of Mr H W PAGE at St. Mary's Hospital. In each a painful swelling of a knee ensued a few weeks after injury, the symptoms were severe and tapping caused some improvement but recovery did not occur until the joint had been washed out with a weak solution of carbolic acid A diplococcus was found to be present which produced a polyarthritis in rabbits The conclusion of the whole matter is that in very many diseases caused by microbes morbid conditions of the joints may occur The joints may be affected in any one of four ways. Firstly, only the toxins of the micro-organisms may reach the joint, giving rise to a not very severe form of arthritis which tends to subside and which results generally in complete recovery of the joint. In a second form the special microbe of the disease is present in the joint and the result will vary according to the micro organism In some cases, as with the pneumococcus, suppuration is very likely to occur, with destruction of the joint, in other cases a more chronic process is set up, leading to much plastic exudation in and around the joint and generally ending in fibrous, or even bony, ankylosis, while in others, again, the inflammatory process is much less severe and more or less complete recovery may follow In a third group of cases there are, in addition to the specific organisms, one or more varieties of the ordinary septic cocci, and there is a further group in which these septic organisms are present alone In these two classes of cases extensive and severe suppuration is certain to follow

As to treatment, Mr MARSH recommends that in the mildest "toxic" forms rest on a splint is probably all that is required. In the microbic cases with effusion into the joint the fluid should be at once removed with an aspirator or by an incision and the joint should be freely irrigated with antiseptic lotion In the form with much plastic exudation the prognosis is unfavourable as to complete recovery, but rest on a splint will be followed by firm ankylosis and this is probably the best that can be hoped for, any injudicious attempts at movement will almost certainly be followed by an aggravation of the symptoms and a postponement of convalescence When septic organisms are present the only hope of doing any good depends on early evacuation of the contents of the joint with free irrigation. Mr MARSH's lecture has thrown much clear light on a very obscure domain of pathology He has brought order out of chaos and has pointed out clearly the direction which bacteriological investigation should take to perfect our knowledge of infective arthritis.

◆

The London Water Board

THE comparative calm which followed the political excitement attending the debates on the Education Bill materially helped the Government to expedite the consideration of the Metropolitan Water Bill, and a certain prestige and elation which the Ministers experienced doubtless favoured the rapid settlement of a less contentious measure. The permanent clerks of the Local Government Board had great reason to desire the success of the measure and as no member of the Opposition had in any way mastered the subject the graceful concessions which Mr LONG was willing to make in minor matters resulted as he wished in insuring the rapid passage of the Bill through Parliament. Now, having received the Royal sanction, it has become the Metropolis Water Act 1902 (2 Ed VII., Ch 41) Such is in unvarnished language the story of the quick and easy passage of the measure through Parliament The first effect of the Act will be the formation of the Metropolitan Water Board, the members of which are appointed under regulations provided in the Act, the details of the election having been left for the arrangement of the Local Government Board the only point which it is necessary to mention here is the fact that with one exception (that of the Thames Conservancy Board) all the authorities which have the power of election are left entirely free and unfettered in regard to the representative whom they appoint It is not necessary for them to elect any member of their own body

The Metropolis Water Act having come into force it is obviously the duty of those concerned to make the best they can of it We pointed out in sufficient detail our objection to the Bill when it was introduced and since that time we have made direct appeals to the Government to reconsider the question in the light of facts which we had brought to notice The Members who had charge of the Bill disregarded our appeals and all we can now do is to advise as to the best course to be taken under the new conditions which have been called into being by the Act From a purely political standpoint it is probable that the Ministers in the measure which has now become law have shown more statesmanship than appears in any previous attempt which has been made in this direction It must also be conceded that the question itself was forced upon the Government by the constant agitation of the London County Council and the fact that enormous sums of money were annually spent by that body and by the water companies in Parliamentary and legal procedure, the Bill for which the people of London had either directly or indirectly to pay It may be further urged in favour of the Act that it does actually, though in a somewhat cumbrous manner, provide for the representation on the Water Board of all the various interests at stake. On the importance of this general principle we have constantly insisted.

The authorities in Water London are now called upon to elect the first members of the Metropolitan Water Board. The successful working of the Act will depend in great measure on the representatives chosen to carry out the important work allotted to them and much will be decided by the character of the start which is made. The first duties which the Board will have to undertake have reference to the purchase of the water companies' undertakings, and on the successful conduct of the case for the purchasers pecuniary interests involving large amounts necessarily hang The water companies have had for years the benefit of the advice of a great majority of the most able and eminent e arrived in Canton on a Thursday, but, unfortunately uld not get on to our home that night We slept in a bed eviously occupied by one who six weeks before had an tack of dengue and still had pains But the bedding attresses, &c., had not been sterilised, although the sheets d been changed. We met, also, one other person who eight eeks before had an attack and still had pains Neither of s were bitten by mosquitoes, which are blamed by the hinese for transmitting the disease On Friday we returned Fatshan and next day my wife suddenly collapsed with all e signs of the disease and in a few hours I followed. My ttack was very light and in a week I resumed my hospital uties, although rather hampered by pains. Almost all the rugs mentioned in the books I have tried on myself or my hinese patients but with little success Perhaps ammoniated incture of quinine, in half to one drachm doses, gave the best esults but practically nothing touched the pains But in easoning about the conditions of the disease in our own case nd comparing our experience with that of a colleague who ad returned from Japan with us and escaped I came to he conclusion that we had been infected by sleeping in an nsterilised bed. My colleague slept in one not previously ccupied by an infected person and has been entirely free. Then, further, I noticed that when my wife recovered a little nd went to Canton she was entirely free from pain. I, staying at home, continued to have them. She occupied an uninfected bed but on the next day after her return her pains were almost as bad as ever I therefore concluded that she was reinfected by sleeping in her own bed. So I suggested that we should take a bath in hot water and some fairly strong disinfectant, and that meantime all mattresses, bedding &c., should be exposed to the sun during the day This was done. After two days of such treatment all our pains vanished, nor have they returned We were not taking drugs. This simple line of after treatment I have, with entire success, carried out with my Chinese patients, as with 'medicine water' it is easy to persuade them to sponge themselves down and to sterilise, in the hot sun we have here, all their beds and clothes. I give simple tonics when necessary The treatment is apparently as effective as simple. I feel convinced that one reason for the long continuance of pains is the nightly re infection. This is quite in keeping with the fact that there is a fine desquamation of the skin often prolonged over two or three weeks in some. The sun evidently speedily kills any infective germs in the desquamated skin dust"

A HOSPITAL FOR PAYING PATIENTS

ON Jan. 9th the Duke of Northumberland opened the hospital for paying patients at Fitzroy House Fitzroy square, London, W, which has now been partly rebuilt and completely renovated. In 1877 Sir Henry Burdett suggested in a letter to the *Standard* that an association should be formed for the purpose of founding a hospital for well to-do patients to which admission should be by payment only A little later a public meeting was held at the Mansion House and ultimately the Home Hospital Association for Paying Patients was incorporated in 1878 A sum of over £20 000 was contributed by those interested in the movement and in 1880 the first home hospital was opened in Fitzroy square. Later the association acquired the freehold of the neighbouring house and a lease of other adjacent premises Fitzroy House, as this home hospital was called, has for 22 years done much work for middle-class patients, for it has always been conducted on a system which provides that each patient shall be charged but little over the cost price for his accommodation and shall pay and be attended by, his own medical man From first to last 5376 patients have been under treatment in Fitzroy House. Last year it was recognised that the hospital must be reconstructed and largely rebuilt so as to provide a perfectly equipped modern hospital. For this purpose it was found necessary to raise £10,000 and of this about £2300 have already been subscribed, leaving about £7700 yet to be raised. The work of renovation has been now completed and the new Fitzroy House contains about 40 rooms, 30 of which are bedrooms. The floors have been covered with papyrolith, which amongst other things contains asbestos, paper pulp, sawdust, and magnesite. This is laid like a cement and forms when dry an extremely hard and impervious surface. A model operation room has been provided on the top floor, with a north vertical light and a top light in addition. The walls and ceiling of the operation theatre are lined by six inch glass tiles All the rooms are fitted with electric light and the whole hospital has been decorated and fitted in a very artistic manner A passenger lift working by electricity renders easy the removal of a patient from one floor to another In its present condition the building is well suited for the purpose for which it has been designed—namely the nursing at moderate rates of middle-class patients The fees charged are inclusive of everything except medical attendance and range from four to ten guineas per week. The hospital is self supporting—in fact, a very small profit is made, for the management endeavours to carry it on at as low a rate as is possible without incurring a debt, and yet the patients have all the attractions and comforts and more than all the medical conveniences of a well appointed house. It is pointed out that the hospital is to a certain extent of the nature of a charitable institution, for the money for renovating the building has to be provided by donations but that, inasmuch as the fees charged to the patients only just suffice to maintain the hospital, it is really self supporting Certain privileges in the way of priority of admission are granted to those who subscribe 20 or 50 guineas. There is, no doubt, a future for institutions such as this when conducted on right principles, for the average private house is ill adapted for sick nursing of any kind, and especially for operations It is felt that there is a need for self supporting pay hospitals in which a lower charge is made than four guineas a week, and Sir Henry Burdett suggests that pay wards should be located in ordinary hospitals and that a two-guinea or a 50*s* minimum fee per week would suffice to cover the cost of maintenance, while the patient could select any medical man he preferred, the medical fees being paid out of a fund formed by putting aside 10 per cent. of all moneys received. The question as to whether this percentage would provide sufficient funds for the purpose appears to rest on the supposition that in many cases more than £2 10*s* would be charged, as the scheme suggests that all the patients should pay what they can afford but in no case less than the above sum.

THE COLORIMETRIC DETECTION AND ESTIMATION OF BORIC ACID

SINCE it is probable that some day—and already we have waited long—the Government may be led to adopt the recommendation of the Foods Preservatives Committee to the effect that the use of boric acid should be altogether prohibited in milk and that the quantity of the preservative should be restricted in butter and cream, it is desirable that we should be in possession of a trustworthy process for the detection and estimation of boric acid in foods. According to Mr C E. Cassal and Mr Henry Gerrans, analysts engaged in the examination of foods under the Sale of Foods and Drugs Acts, the old turmeric test may be improved considerably by adding oxalic acid. They apply the test for free or come from a polluted source. Authoritative warnings as to the dangers from the pollution of oyster beds by sewage have in the past been issued, as Dr Fraser says, only to be ignored. Dr Fraser makes out a strong case in favour of the oysters having been the origin of the outbreak. There is no other conclusion left in the face of the following facts—(1) that all the 25 persons attacked ate oysters about the time they must have contracted the disease, (2) that these oysters came from the Emsworth oyster fisheries, (3) that the fisheries were open to contamination from the specific organism of typhoid fever, and finally (4) that there is no other condition common to all the cases which would account for the outbreak. It is pointed out that whatever lines legislation should take oysters, cockles, and mussels should all receive attention Dr J T C Nash, the medical officer of health of Southend, has clearly traced outbreaks of typhoid fever through sewage polluted cockles from Leigh and bacteriological examination has shown that the momentary immersion of sewage polluted cockles in boiling water does not destroy the materies morbi Dr Fraser remarks that in connexion with prospective legislation there is also the question of imported shell fish to consider, for all attempts to protect our own fisheries would be defeated if no precautions whatever were observed in regard to the shell fish imported from foreign sources

THE SHROUD OF CHRIST

IN THE LANCET of April 26th, 1902, p 1216, we gave a short *résumé* from the pen of our Paris correspondent of the paper read by M Vignon before the Paris Academy of Sciences upon the Holy Shroud of Turin. We also pointed out in an annotation that it was by no means beyond the bounds of probability that a dead body would give off emanations or "vapours" which would affect a linen cloth which had been prepared with aloes and unguents. In a work recently issued[1] M Vignon has expanded his paper and has gone exhaustively into the questions (1) whether the markings on the shroud are painted, (2) whether there do exist substances in or upon a dead body, especially that of a person dying a lingering and painful death, which could affect preparations of aloes, and (3) whether the markings on the shroud correspond to those known to have been inflicted on the body of Christ according to the Scriptures There seems to be little room for doubt that M Vignon has established that the outlines on the shroud are due to the emanation of vapours, and he suggests that these impressions might be called "vaporographic" prints He certainly seems to have proved that the material must have been the shroud of a crucified person, and not only of a crucified person but of one who underwent also scourging and the other accompaniments of death which by both the Scriptures and tradition are ascribed to the Passion of Christ. As to whether or not the Holy Shroud be the actual shroud in which was wrapped the body of the Saviour there is, indeed, no proof, but according to M Vignon's deductions there would seem to be a high degree of probability Aloes, according to his experiments, fulfil the twofold conditions necessary for a substance which could produce such impressions as those found on the Holy Shroud. It remains to determine what vapour the dead body would give off which could affect or discolour aloes in the manner shown on the shroud It is asserted that in order to fulfil these conditions it is only necessary that the body should be covered with pathologic sweat and especially the sweat of fever It is well known that in morbid sweat the increase of urea is quite astonishing and M. Gautier has stated that urea may be produced so abundantly in morbid sweat that it form crystals on the surface of the body Again, the same writ says that viscous sweat strongly charged with urea will b given off by any fever patient in a crisis of pain. Th transformation of urea into carbonate of ammonia provides vapour which would act upon aloes in the way indicated Experimental observations point to these conclusions being correct and M Vignon and his collaborator, M. Colson are convinced that a linen cloth which had been saturated with oil and aloes would, after a lapse of years o rather centuries, look like an ordinary cloth except i those parts where it had been subjected to the action o ammoniacal vapours In these parts it would be covered with blotches varying in intensity, more or less shaded a the edges, of the colour of rust or rather resembling blood stains, giving just, in fact, the aspect of the impressions presented by the Holy Shroud of Turin The phenomenon therefore, if thus accurately described, is analogous in some respects to the effects of the emanation of vapour from metals on the sensitised plate and attributed by Dr W J Russell, F R.S, to the formation of peroxide of hydrogen. Accordingly, the phenomenon of radio activity would appear to have played no part in the production of the impression o the Holy Shroud. Whether M Vignon is right or wrong h certainly has pursued an exceedingly interesting line o research which has yielded very remarkable results, while his deductions are decidedly ingenious

THE EPIDEMIC OF DENGUE FEVER IN CANTON, CHINA

DR W J W ANDERSON of the Wesleyan Mission at Canton writes to us under date Nov 24th, 1902, as follows —"The year 1902 has been an exceptional one in and around Canton. In the early months of the year there was prolonged drought followed by a severe outbreak of cholera. Then the rain fell and plague raged like a fire amongst the people. In Fatshan (near Canton), a city as large as Leeds it was no uncommon thing to find two or three in the family having died from the dread disease In June, July, and August another epidemic swept over the delta and I am not far wrong in estimating that dengue temporarily claimed 95 per cent. of the population as its victims, foreign and Chinese alike. Extensive opportunities for observation of the disease amongst all classes have convinced me that it affects all alike —rich and poor, foreign or native True, there are some differences, as the fair skin of a foreigner allows of the rash being much more pronounced, while the thick tough skin of the native does not seem to lend itself to the development of a good rash and the yellow pigment of the skin obscures its redness somewhat But for severity of pains, height of fever and general malaise, all have suffered alike The disease is practically never fatal I have heard of one old man who seems to have succumbed to the disease. Nevertheless it is a distressing condition because of the pains they are so severe, continued, and crippling. In this epidemic the ankles and wrist-joints have been specially affected and pains have been felt even after the elapse of eight or ten weeks Any immunity that is conferred is probably of short duration only, as second, and even third, attacks have come under my notice. As to the cause, it is probably a germ The disease is certainly intensely infectious and is transmitted from man to man and conveyed in fomites. It does not appear to be carried any great distances by the air or to be affected by dry or wet atmospheric conditions, so long as it is hot This is essential. I am inclined to believe that the germ can live a long time in unsterilised things like blankets, bedding, clothes, &c., at the same time it is exceedingly easy to kill. My own experiences afford an excellent illustration, for I returned with my wife from Japan in splendid health after a holiday died 72 hours after the operation. Dr Lund thinks that the rupture of the intestine was from within and the result of a sort of *contre-coup* In cases of abdominal injury perforation may occur from within the fluid contents of a loop of gut confined for the time in a narrow space are by the impact thrown into a state of tension and are forced through the intestine Several cases are recorded of perforation from falls on the back. In all of these the perforation was at the beginning of the duodenum, where the gut is held down by a fold of peritoneum and has but little mobility

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST

IN the *St James's Gazette* of Jan 10th there appeared a paragraph, headed Coroner Troutbeck Replies to his Critics,' which reported a speech made by Mr Troutbeck t an inquest held in Wandsworth on the previous day As ar as we were compelled to criticise Mr Troutbeck his eported words contain no reply whatever According to the t *James s Gazette* he said that—

> He had recently been carrying out a policy of considerable moment o the public. A long time since the London County Council came o the conclusion that many of the post-mortem examinations made ere a waste of money because they were not properly carried ut, and without obtaining legislation on the subject the Council ad done what they conceived to be their duty to the public by nabling coroners to engage the services of a skilled pathologist. t was perfectly clear that a great many medical men in the neighbour ood thought that the law was made for the good of medical practi ioners and not for the good of the country but that was a position hat he (the coroner) would not *for one moment* recognise. It had lways been held in this country that interests of any particular class ere all very well so long as they did not clash with the com nunity as a whole the moment they did that class must give way He was bound to carry out his duty without fear favour or affection nd to the best of his skill and knowledge. If it was true as had ppeared in print that his policy as it affected local medical men was n attack on the liberty of the people," it was time they changed it For his own part he believed a coroner possessed the discretion of alling what medical evidence he chose, and he was bound to exercise hat discretion for the good of the inhabitants and the country That was the policy he meant to adopt and he did not mean to change from his purpose on account of any suggestion that Battersea money should be spent on Battersea doctors" and so on such assertions would not influence him in the slightest degree. The only thing that could influence him was what was the best evidence to put before the jury to get the best results.

Mr Troutbeck's words, as recorded above leave every issue unanswered that has ever been raised by thoughtful unbiased persons No one doubts that the services of a skilled pathologist—we are not referring to Dr Ludwig Freyberger of whose scientific merits we have not expressed, and do not express, any opinion—may be of value in special cases. It is probable that the expert ought to be called for by the jury and not by the coroner but, passing the point over, why are so many inquests in Mr Troutbeck s district attended with peculiar circumstances? No sensible person has ever raised the cry of ' Battersea money for Battersea doctors" or thinks that the law is made for the good of the general practitioner, the skilled pathologist, or the coroner. Reasonable critics of Mr Troutbeck's position say that if he neglects to call as a witness at an inquest the medical man who has attended the case he does not do his duty to the community He does not obtain his verdicts upon the best evidence and his procedure may result in some awful miscarriage of justice. We congratulate Mr Troutbeck on the unwavering courage and cold impartiality with which (he is made to say) his actions are inspired, but we would point out that he appears simply to be carrying into effect the orders of the London County Council, in accordance with a promise made before he accepted his recent appointment. When if ever, Mr Troutbeck seriously replies to his critics he will have to prove the legality of his actions He will have to show that the County Council has the power to enter into an agreement with him whereby he should act contrary to the law of the land. It will not be sufficient and it will not be straightforward, to suggest that there is nothing behind the agitation against his conduct save a greediness on the part of "Battersea doctors for Battersea money" This is an unworthy innuendo on the part of a professional man against a group of professional men, and we trust that Mr Troutbeck will state publicly that he has been misreported.

THE TRANSMISSION OF SMALL CHARITABLE CONTRIBUTIONS

MR J BERNARD LAMB, the secretary of the Royal Medical Benevolent College, has sent us a letter in which he suggests a scheme for the transmission of small contributions to the larger hospitals and charities in London. Mr Lamb s scheme is as follows (1) a department of the Charity Commission is to be authorised to receive contributions and the moneys received, less a percentage for poundage and postage are to be handed to the charities for which the subscriptions are sent once or twice a year, and (2) the issue of post-card cheques of values ranging from 6*d* to £1 1*s*. payable only to the Charity Commission. The scheme seems to be practicable though it may require modification. As the writer of the letter points out, a feeling certainly does exist among some people that small amounts are not worth contributing towards the funds of a charity Moreover, when adverse circumstances compel subscribers to curtail their list of contributions they invariably cease to subscribe altogether Facilities for remitting small contributions are not numerous and a scheme like Mr Lamb s ought, if carried out, to have the effect of adding considerably to the income of the various charitable institutions.

FACIAL PARALYSIS IN SECONDARY SYPHILIS

ONLY a limited number of cases of facial paralysis in secondary syphilis has been recorded. Several explanations of the paralysis have been given. The usual one is pressure on the facial nerve *from inflammation* within the Fallopian canal, but pressure at its origin from the medulla produced by a patch of meningitis and pressure after its exit from the canal produced by lymphatic glands have also been invoked. Finally syphilitic infection possibly produces neuritis of the facial nerve, as it does of *other nerves* So far the explanations are only hypothetical, in no case has the opportunity of making a necropsy arisen. At the meeting of the Société Médicale des Hôpitaux of Paris on Nov 21st, 1902, M Georges Thibierge and M. Paul Ravaut related a case of facial paralysis in secondary syphilis which derived additional value from the fact that the cerebro-spinal fluid was examined—for the first time in this condition. On Nov 18th a girl, aged 19 years, went to hospital with mucous patches on the vulva which had existed since the middle of August. She had a pigmentary *syphilide* on the neck, enlarged cervical and inguinal glands, and mucous patches on the lips and *tonsils* On Nov 17th she complained that since the previous day she had had some difficulty of speech and mastication, with lacrymation of the right eye There was right facial paralysis, the furrows on the right side of the face were effaced and the eye could be shut only slowly and incompletely Hearing was not affected. On the 19th the paralysis was a little increased and lumbar puncture was performed. The fluid obtained showed abundant leucocytes and a few polynuclear and mononuclear cells. The importance of this result is rendered greater by the fact that examination of the cerebro-spinal fluid of five women in the secondary stage of syphilis revealed no such marked meningeal reaction. In three of them who complained of headache the fluid contained no cells, in the two others, of whom one had slight iritis and the other paralysis of the third cranial nerves, the fluid showed only slight lymphocytosis. Lymphocytosis of the cerebro-spinal fluid has the value of an anatomical *fact* and shows the existence of a meningeal reaction. In the case described above it points to a meningeal lesion as the cause combined boric acid in milk or other foods by first drying and burning the residue to an ash. It is well to add a little caustic baryta solution before evaporation and incineration as otherwise small quantities of boric acid might be lost. The ash is treated with a few drops of dilute hydrochloric acid, then with a saturated solution of oxalic acid, and, finally, with an alcoholic solution of curcumin or turmeric, and the mixture is dried on the water bath and the residue is taken up with a little spirit. The spirit will be coloured a more or less intense magenta red if boric acid is present Mr Cassal and Mr Gerrans state that they have been able to employ this test for the determination of the actual amount of boric acid present. If their observations are confirmed this method should be of obvious service

THE CONTAGIOUSNESS OF CANCER

IN a leading article in THE LANCET of Dec. 6th, 1902, p 1558 we reviewed the reasons for thinking that, in spite of the fact of our ignorance of the real etiology of cancer, we were justified in looking upon it as contagious and in taking all those precautions to prevent its spread which that theory of its origin would suggest. Dr A. T Brand of Driffield has drawn our attention to the address which he delivered last May on the occasion of his installation as President of the East Yorks and North Lincoln branch of the British Medical Association. In this address Dr Brand maintains the contagiousness of cancer and supports his contention with many of the arguments which we advanced in the leading article referred to, and he quotes an instance of apparent contagion occurring within his own knowledge It is in the suggestions for prophylaxis that Dr Brand's address is especially interesting In addition to most of the precautions which we advocated, such as destruction of the dejecta and dressings, he mentions "notification." This might prove to be a valuable measure as it would enable precautions to be taken against the spread of the malady and would give us more accurate information as to the localities where the disease arises than can be obtained from statistics as to the places of death from cancer

SCOTTISH POOR-LAW MEDICAL OFFICERS' ASSOCIATION

THE report of this association for the year 1902 states that during that period the committee was occupied with a number of important questions The secretary (Mr W L. Muir, 1, Seton terrace, Glasgow) was summoned before the Committee of the Privy Council which has for some time been considering the subject of the sale of poisons His evidence on that occasion was to the effect that in the Highlands, islands, and country districts where there were no druggists it was necessary for medical men to supply the public with all drugs required, poisonous or otherwise, and it was a serious hardship for a medical man to be found guilty of "infamous conduct" by the General Medical Council because in his absence someone in his surgery had supplied a scheduled poison to a member of the public The secretary was also summoned before the Scottish Local Government Board as a witness in its inquiry as to the medical relief of the poor The general character of his evidence was that it was absolutely essential that the Poor law medical officer should have a more secure tenure of office than at present, with an appeal to the Local Government Board against unjust treatment, that he should have the power of ordering invalid diet, stimulants, and the like, without the same being vetoed by the inspector of poor (an official corresponding to the clerk to a board of guardians in England), and that for all fractures, midwifery, and other exceptional cases there should be extra fees The Bill for the amendment of the Local Government (Scotland) Act, promoted by the association, was persistently blocked by one of the Scottish Members of Parliament and did not reach the second reading The Lord Advocate's Bill to amend the Local Government Act likewise never reached a second reading, having been blocked by the same Member Both Bills will, however, be introduced again next session.

THE DISTRIBUTION OF PLAGUE

AS regards the Mauritius a telegram from the Governor to the Earl of Onslow, acting for the Secretary of State for the Colonies, received at the Colonial Office on Jan. 6th, states that for the week ending Jan 1st there were 9 cases of bubonic plague and 5 deaths from the disease.

THE TREATMENT OF ABDOMINAL CONTUSION WHEN RUPTURE OF THE INTESTINE IS POSSIBLE

WE have recently called attention to the difficulty and even impossibility of diagnosing rupture of the intestine in cases of abdominal injury The great importance of early operation has led American surgeons to advocate the performance of laparotomy within a few hours of the injury in all serious cases of abdominal contusion [1] In the *Boston Medical and Surgical Journal* of Nov 27th, 1902, Dr F B. Lund relates six cases of early laparotomy in rupture of the intestine with four recoveries—eloquent testimony of the value of this treatment He points out that beyond the fourth or fifth hour after injury every hour adds to the danger, and that the surgeon cannot afford to wait for certain signs of perforation In his successful cases the interval between the injury and the operation was three, five, nine, and 16 hours respectively, in his unsuccessful cases 18 and 24 hours respectively One case presented the remarkable feature that apparently there was no contusion of the abdominal wall but that there was of the back. The patient was a man, aged 40 years, who was taken to hospital six hours after he was struck in the back, below the left shoulder blade, by the shaft of a wagon and knocked down He felt faint for a time. Severe abdominal pain, chiefly above the umbilicus, followed. He soon got up and was able to walk three quarters of a mile A cup of tea which he drank brought on vomiting and the pain increased. On admission the pulse was 92, thready, and of low tension, the temperature was subnormal, the lips were pale and the face was ashen The abdominal wall showed no evidence of injury The abdomen was distended and everywhere was rigid and tender There was no dulness, even in the flanks. On the back, over the left tenth rib, about three inches from the middle line, was a red contused area. Immediate operation was advised but declined. A high enema brought away but little fæces. A quarter of a grain of morphine injected subcutaneously gave only slight relief He grew steadily worse and 18 hours after the injury consented to operation. On opening the abdomen much dark brown fluid, evidently bile-stained, and flakes of fibrin and particles of food escaped The peritoneum of the small intestine was congested and covered with fibrinous exudation. A perforation which easily admitted the forefinger was found in the jejunum opposite the mesenteric attachment, extending downwards from it in the long axis of the bowel was a peritoneal tear one and a half inches long Owing to its position and to abdominal rigidity the perforation was sutured with difficulty The patient recovered well from the operation, the pain ceased, and the pulse improved, but on the second day after the injury severe diarrhœa began. It was controlled by opium and he improved On the third day he again became worse and he country, but Dr Bleyer's observations would suggest a further trial in combination with the open air treatment

[1] THE LANCET Jan 25th, 1902, p 247

THE RISKS OF SHAVING

THE use of soap lather prior to shaving the beard is regarded merely as a means of facilitating the troublesome operation. Soap is said to extract the oily matters from the hair and thus to render it brittle so that the blade of the razor saws through it easily, for after all shaving is a delicate sawing process. With sensitive skins of course a soap of good quality and preferably free from alkaline excess is desirable On the other hand, it might be thought that an excess of alkali would prepare the beard more readily than a pure soap or superfatted soap The corrosive effect of alkali, however, leaves no doubt as to which description of soap should be used. Soap probably plays a more important rôle than that of a saponifier of the natural oil of the hair In spite of the fact that those who use the razor frequently cut themselves yet it is rarely that anything more serious than a cut follows the slight wound generally healing quickly, and the risk of septicæmia arising in this way would seem to be almost *nil*. In the majority of cases therefore it is clear that the razor blade must be bacteriologically clean—i.e., free from septic matter—which may be attributed to the fact that probably it is dipped into hot or sterilised water before use or else that the soap lather is antiseptic. The latter explanation seems the more probable of the two. The amount of soap rubbed on the skin is considerable if the shaving is to be in any degree comfortable, and soap has considerable antiseptic power, a 6 per cent. solution being sufficient to destroy the typhoid bacillus. There can be little doubt, therefore, that the skin is rendered sterile by the liberal application of soap, and this fact is in favour of any cut that may be made remaining healthy and without any serious consequence. In a word, soap in the operation of shaving not only facilitates the process but plays the same valuable rôle when the shaver is unlucky enough to cut himself as does the antiseptic in surgery

A HOSPITAL FOR THE INSANE IN SYRIA

THE treatment of lunatics in the East has not yet fully emerged from the clouds of ignorance and barbarism which have surrounded it for ages. One of the first reformers who attempted to introduce the methods of humanity and science in this field in the near East was Mr Theophilus Waldmeier a gentleman resident in Syria, who commenced in the spring of 1896 the work of helping and providing for the numerous sufferers from mental disease in Syria and Palestine. His efforts were crowned with success and within two years a hospital for the insane was built near Beyrout, on the slopes of the Lebanon Mountains. This institution has been in full working order and has been doing good work for two years In the fourth annual report recently issued there is an account of the institution and of its work for the year ended March 31st, 1902 The building which includes wards for male and female patients, is of stone, the grounds which were hitherto barren, have been cultivated, and at the time of the report (1902) there were about 35 patients in the hospital Patients come and go without much difficulty being experienced as relatives are sometimes prone to take them away before recovery is complete. "One poor Jewish woman was brought to the hospital suffering from acute mania. She was left by her relatives apparently under the idea that she would be miraculously healed in a day or two by the doctor After a few days they returned and found her about the same, and being disappointed at this they immediately took her away probably to put her in some dungeon or cave noted for casting out evil spirits, there possibly to die in chains." Fortunately, adds the report, such cases are becoming rarer as the results of the work of the hospital are becoming more known amongst the people. 14 patients were discharged as recovered during the year New wards are nearly completed for increased accommodation, so that the hospital will shortly be able to house 100 patients. 52 patients were admitted during the year The amount contributed by the relatives of patients towards support and maintenance suffices to meet only about one-fourth of the cost Charitable aid has been received from Great Britain, the United States, Canada, Switzerland, and other countries, and from the Turkish governing authorities of Mount Lebanon. The medical administration is under the care of Dr O Wolff and Mrs. Wolff. The address of the secretary in London is Mr Francis C Brading 35, Queen Victoria street E.C, to whom charitable donations, gifts of books and articles of clothing, and inquiries may be addressed Cheques should be crossed London, City, and Midland Bank.

SOME CURIOSITIES OF MEDICAL PRACTICE IN INDIA

A CORRESPONDENT has sent us from Calcutta a collection of anecdotes bearing on the supposed efficacy of contact with live animals in the treatment of certain morbid conditions. Some 60 years ago, he says, there was a great Kaviraj or Bengali, physician in Nuddea whose name was either Janardan or Jaggannath. This worthy followed the methods of the ancient school of Indian practitioners and was, moreover, a specialist in the 'animal cure.' When sent for to attend a young man suffering from asthma he announced that he would employ the "goat treatment." Ghee prepared with goat's flesh was administered internally and a goat which made itself disagreeably perceptible to the nasal organs was brought into the room three times a day The patient inhaled the odour, made use of the animal as a pillow, hugged it during his paroxysms, and recovered in a few days. The "reptile cure' was prescribed for a patient attacked with violent headache. A large snake was caught in the jungle and after its jaws had been properly secured it was wrapped round the sufferer's head The poor snake died in a few minutes but the patient made a rapid recovery Summoned to an urgent case of retention of urine the same specialist brought with him some live frogs caught by the wayside and poured over the patient's navel the juices squeezed from one of them, after which he tied another frog in a muslin bag and applied it to the navel The sufferer is alleged to have been able to empty his bladder forthwith

MR LONG AND THE IMPERIAL VACCINATION LEAGUE

ON Wednesday afternoon, Jan. 14th, the President of the Local Government Board received an important deputation from the Imperial Vaccination League. The deputation was introduced by Sir William S Church President of the Royal College of Physicians of London, and numbered among the speakers Sir James Crichton Browne, Professor T. Clifford Allbutt, Dr F T Bond (representing the Jenner Society) Dr J C. McVail, Mr Devitt, Mr Debenham, the Chief Rabbi, Alderman Menlove, Mr R. Brudenell Carter Dr T D Acland, Sir William H. Broadbent, and Dr J G Glover The speakers from various points of view urged upon Mr Long the necessity for legislation in respect of revaccination and the provision of a better supply of lymph. Mr Long in a reply of an admirably satisfactory character, declared himself in favour in forthcoming legislation of making the county councils and borough councils the vaccination authorities for the future—a view with which our readers know we are of the paralysis—a hypothesis in keeping with the symptoms, for the absence of auditory and gustatory troubles points to a lesion of the nerve before it entered the temporal bone and before its union with the chorda tympani. In the discussion which followed M Widal pointed out that the facial nerve from its origin to its entry into the auditory canal is in contact with the meninges, and that the question whether the neuritis gave rise to meningitis or *vice versâ* was unsolved. The period of the syphilis at which the paralysis occurred could not be exactly determined but it was probably about the fifth or sixth month.

OYSTERS AND TYPHOID FEVER IN AMERICA

AS in France and in England so also in the United States of America the spread of typhoid fever by contaminated oysters is a contingency which, as has been again proved, may occur A special investigation has been held in respect of 72 cases of typhoid fever recorded last autumn in Atlantic City During the season this popular resort accommodates some 200,000 persons. In one third of the cases the patients were visitors staying at different hotels. Of course there were exaggerated rumours, and as the interests of the town depended on its holiday visitors that was a matter of grave concern Consequently Dr Abbott, bacteriologist of the University of Pennsylvania, and Dr Henry Jeffmann were called in consultation It was found that the water used for drinking came from different sources All the hotels had artesian wells and the private houses had the town supply The cases were scattered in different parts of the town and no special and similar sanitary defects were found. An important discovery, however, was made. There are sewer pipes that cross a canal—the Penrose Canal, these were broken and allowed the sewage to escape into the water Near at hand three of the largest oyster dealers are in the habit of "refreshing" their oysters for market in the water of this canal. All the hotels where cases of typhoid fever occurred purchased their oysters from these dealers and there was not a single case of the disease in any of the other hotels. No sooner was this ascertained than a sort of quarantine was imposed on all the waterways communicating with the Penrose Canal and the broken sewer was promptly repaired. There have been no more cases of typhoid fever and the local authorities, together with the experts whom they consulted, are convinced that they have discovered and removed the cause of the outbreak.

MUNICIPAL BACTERIOLOGICAL LABORATORIES

IT is invariably found that wherever bacteriological laboratories have been installed the result has been a decided gain to the community We have advocated the foundation of municipal bacteriological laboratories like that at Lambeth which, since its inception in 1899, has been the scene of no less than 2037 bacteriological examinations. Dr J Priestley, the medical officer of health of Lambeth, reports that one reason for the success of this bacteriological laboratory is the great use that is being made of it by the Lambeth medical practitioners, by whom its institution by the late vestry in 1899 has been much appreciated and to whom it has proved of the greatest value. Apart from the question of the bacteriological examination of foods such as milk, ice-cream, and other articles, a bacteriological laboratory affords the medical officer great assistance in carrying out his duties and is of service to the medical practitioner in verifying the diagnosis in doubtful cases of infectious disease In Lambeth the institution of a bacteriological laboratory has been the means of thus verifying diagnoses, with the result that distinct indications are given when preventive measures should be taken In the event of the suspected disease not having been shown by bacteriological examinations to be of an infectious nature expense has been saved in connexion with hospital treatment and disinfection. In fact, bacteriological laboratories in large communities are a *sine quâ non* if medicine is to be truly progressive and the public health is to be efficiently guarded In connexion with this question we may note that the Bristol Health Committee has recently decided that the bacteriological work which had been done in the medical officer's department should be for one year transferred to the University College where it would be carried out by Professor Stanley Kent at a cost of £200

THE THERAPEUTIC IMPORTANCE OF LIGHT IN THE TREATMENT OF TUBERCULOSIS

WE have received the reprint of a paper which appeared in the *Journal of Tuberculosis* for October, 1902. The title is "Light its Therapeutic Importance in Tuberculosis as founded upon Scientific Researches." It is written by Dr. J Mount Bleyer, Vice President of the American Congress of Tuberculosis. The pamphlet consists of 80 pages and is mainly occupied by an elaborate disquisition upon the physical properties of light and the effect produced by it upon vital organisations. The amount of labour involved in collecting material for this contribution must have been immense. In addition Dr Bleyer publishes a number of original observations on the therapeutic applications of light which, if corroborated by other observers, will prove of great value in the treatment of tuberculosis It has been shown by several authorities that colour exerts a very powerful influence on the conduction, radiation, and permeation of heat. White or light-coloured clothes transmit more light to the body than those of any other colour, while black or dark coloured clothes absorb the light and degrade it into the coarser principle of ordinary heat. Dr. Bleyer therefore advises that all clothing for general wear of the tuberculous should be made of lightest coloured materials, preferably all white garments He further states that he has seen "most wonderful results" from the exposure of the entire body in a nude state in solaria built for his patients. "Sun baths" have been adopted in connexion with one at least of the sanatoriums in this country, but this form of treatment has not yet been sufficiently tried to enable any definite opinion to be formed as to its value. Dr Bleyer in 1896 published in the *New York Medical Journal* some remarks on "electric arc cromolumes for generating violet rays of light as an adjunct to the treatment of tuberculosis." He now states that he has employed coloured rays of light with a successful issue in 60 cases of tuberculosis, of which he reports 40 were "cured," and in 20 "the disease was arrested to such an extent as the pathological changes present when they came under treatment would admit." He describes in detail the apparatus he employs for generating and applying the rays. Before criticising this method of treatment further investigations by other physicians will be necessary Dr Bleyer's results are certainly very striking and his therapeutic processes demand a full trial. Another portion of his communication is also worthy of notice. He undertook a number of physiological experiments to test the value of the different salts of iron in conjunction with 'light administration.' In over 100 tuberculous patients the different iron salts and organic preparations of iron were administered and the patients were placed exposed to the sun's rays and electric arc light The iron salts were found to be taken up most rapidly, producing excellent constitutional effects. After the first week the red blood corpuscles had greatly increased in number and the amount of hæmoglobin was much larger The administration of iron salts in cases of tuberculosis has not been extensively adopted in this country, but Dr Bleyer's observations would suggest a further trial in combination with the open air treatment

THE RISKS OF SHAVING

THE use of soap lather prior to shaving the beard is regarded merely as a means of facilitating the troublesome operation. Soap is said to extract the oily matters from the hair and thus to render it brittle so that the blade of the razor saws through it easily, for after all shaving is a delicate sawing process. After the first week the red blood corpuscles had greatly increased in number and the amount of hæmoglobin was much larger The administration of iron salts in cases of tuberculosis has not been extensively adopted in this om Dr Turnbull, College of Medicine, Newcastle-on-Tyne, nd must be applied for on or before Jan. 23rd.

THE annual meeting of the Neurological Society of London ill be held at 11, Chandos-street, W, on Thursday, an 22nd, at 8.30 P M. The Presidential Address will be iven by Dr J N Langley, M.A., D Sc., F R.S, on the utonomic Nervous System

PROPHYLAXIS

N ADDRESS DELIVERED BY PROFESSOR NOTHNAGEL OF VIENNA AT THE MEDICAL CONGRESS IN CAIRO ON DEC 24TH, 1902.

(*Specially translated for* THE LANCET)

'THE most valuable asset is man." These true and high-minded words were uttered by one of the most enlightened of princes, our deeply mourned Crown Prince Rudolf of Austria. It surely finds an echo in the noble heart of the protector of this congress who is swayed by the same enthusiasm for the human race. It shows the most beautiful sympathy with mankind, and who so loves his fellow man and seeks the good of the State must strive earnestly after the fulfilment of the high ideal put before him in this great saying, both in his profession and in his sphere of influence.

For us medical men this duty becomes a challenge. Medical science must eventually make therapeutics unnecessary, which, though it sounds paradoxical, I feel in my innermost soul to be its true and final mission To put it from the first plainly before you, understand this not therapeutics but prophylaxis, not the healing but the prevention of disease must be the mission of medical men. The following briefly outlined examples will serve as proofs of the truth—nay, of the necessity—of this maxim.

Until quite recently all the efforts of medical knowledge were devoted to the cure of man already diseased. Medical knowledge existed and exists to cure. In former days there was supposed to be one or more definite remedy for each illness and symptom but we have long put away such childish beliefs. It was recognised that the physician must in each case of sickness draw up certain indications for treatment in order to carry out his therapeutics according to definite scientific formulæ. There are three headings of such indications for treatment (1) the *indicatio causalis*, (2) the *indicatio morbi* and (3) the *indicatio symptomatica*—that is, the indication of the cause of the illness and its symptoms. Very rarely are we able to satisfy ourselves as to the *indicatio causalis* chiefly because in only a limited number of diseases is the real cause known. For instance, it has long been acknowledged that the much accused "chill" only prepares the way for the scene of action of the real cause, but does not in itself cause disease. We hardly possess the early beginnings of a dawning knowledge of the etiology of a long list of diseases resulting in the process of metabolism. It is true that, thanks to the wonderful development of bacteriology in the last ten years, we have to a certain extent mastered this knowledge in the case of the large group of acute and chronic bacterial infectious diseases, but, unfortunately, this is but one group in the mass of pathological conditions And in these, as in other cases where the cause is the introduction of a known chemical poison (alcohol mercury, &c.) so for all other pathological conditions we must, respecting the *indicatio causalis* be perfectly clear about one point, which marks the direction in which we must act. At the moment when the medical man sees the patient the pathogenic causes have already produced effects representing the symptoms of disease, which are, of course the signs of irregularity in the normal course of life which prove the existence of illness. But these *functional* reactions of the organism are invariably accompanied by more or less evident organic changes, visible to the naked eye or with the microscope. And treatment cannot, under these conditions, be limited to the eradication of results it must also undertake the further task of curing these diseased organic conditions.

But how about the fulfilment of the second indication for treatment, the *indicatio morbi?* Verily, the deeper we search and the more we discover the marvellous ways in which nature overcomes disease, the more deeply we feel convinced that it can be only in exceptional cases possible for us to overcome pathological conditions by actual cures, that is, by our direct interference. I can cure a case of malaria with quinine, syphilis with mercury and iodides, with the latter also certain affections of the glands, besides certain nerve and skin affections with arsenic, anæmia with iron and diphtheria with the special serum. And thus a limited number of cases could be cited where the medical man really becomes the *master of nature*, but what an infinitely small number compared to the innumerable pathological conditions that exist. The utmost we can do in most cases is to remove what is preventing the work of restoration by nature, or to assist to our uttermost the energy displayed by her One of the greatest strides made by therapeutics in the last century is that the recognition of this fact has become more universal.

We admire the wonders of aseptics, but do not let us deceive ourselves, be the operation ever so daring and brilliant the surgeon has not the power of healing, he can but prepare the way for the readjustment of normal conditions attempted by nature. The words of Ambroise Paré are as true to-day as they were 350 years ago "Je le panse, Dieu le guérit" Even in the case of the most simple operation union by first intention is only brought about by the cells of the severed tissues, not by the mechanical sutures. A catarrh cannot be cured by any local or general treatment, but by the action of the cells of the blood and the lymph stream. The serious functional and anatomical disturbances displayed in cases of typhoid fever, small pox, scarlet fever &c., can up to now only be overcome by the means of defence set up by the organism itself. How our views have in many respects changed. We no longer regard the symptoms of inflammation or of fever as an evil that must be destroyed. We now recognise that these symptoms are in themselves some of the means of defence employed by nature and that only when they appear in excessive degree do they need direct treatment. Look at the marvellous adjustment and adaptation by nature which renders harmless the serious changes occurring in many chronic diseases A defect of the heart can be so influenced by hypertrophy that though it would otherwise inevitably have fatal results yet it may cause no important disturbance for many years. The loss of one kidney can functionally be made good by the increase in size of the other A threatened obstruction of the intestine above a narrowing of the bowel is prevented by rapid muscular development of the walls of the intestine, a change that is often completed within the space of a week. When a blood vessel is diseased collateral circulation carries on the work, one nerve tract will act for another which has been cut And thus hundreds of examples could be brought forward in which the organism undertakes the adjustment of diseased conditions and does its work almost to perfection It is the natural adaptation which takes place unaided in pursuance of the biological laws of the organism which has the power, if not to cure, yet to protect to some extent from further injury But what if the diseased part is not accessible to these influences, in consequence of its peculiar nature and intensity, or because of certain anatomical conditions? What can art do then? The answer is depressing in the extreme, we can then only depend upon symptomatic treatment There is no doubt but that this also serves a great purpose in lessening pain, in bringing peace and comfort Never will medical art be able to dispense with symptomatic therapeutics so long as disease exists.

Digitalis and antipyrin diuretin and atropine, and a long list of other substances, above all others opium and morphia, are invaluable possessions in the treasury of medicine for the accomplishment of symptomatic treatment There can be no doubt of the immense benefit they can be to a sufferer when they are properly employed They may even accomplish so much that the patient may dream that they have effected his cure For so long as he is free from suffering in his anatomically changed organs he cares not whether his heart be big or small his life smooth or troubled And when hydrotherapy succeeds in the case of a tuberculous patient suffering from fever, or one of typhoid fever or pneumonia in improving the temperature and circulation, or in nerve cases and subjective conditions, it may be considered indispensable And so countless examples might be given to prove the value of symptomatic therapeutics But in the end we come to this—they cannot cure because many in accord He also gave a good character to the available supplies of lymph The various arguments adduced by the well informed speakers, as well as Mr Long s statesmanlike reply, will call for further report and notice from us

CASSIA BEAREANA AND THE MALARIAL PARASITE.

IN THE LANCET of Feb 1st, 1902, p 282, we published a communication from Dr D R. O'Sullivan Beare upon a native remedy which he had used with great success in blackwater fever and in cases of remittent fever The remedy in question was a species of cassia which has been named "cassia Beareana." Messrs Thomas Christy and Co, to whom Dr O'Sullivan Beare sent a supply of the root and who prepared a fluid extract thereof, now send us two communications on the matter One is from a lady who had to leave Ceylon on account of malaria and who came home by the advice of the Government medical man at Newasa, Eliya. She had seen an account of the remedy in the *Ceylon Observer* and at once applied for some of the fluid extract which she took without apparently any medical advice. But she improved so much after taking it that she has determined to go back to Ceylon The other communication is from Dr C C Beling of the New Jersey State Hospital, Morris Plains, N J, U S A, who wrote to Messrs Christy and Co as follows —

> DEAR SIRS —In reply to my request of Feb 11th 1902 you sent me a 4-oz bottle of cassia Beareana. I tried the drug on some cases of malarial fever with gratifying results I have tried to procure more of the drug in New York through the State Hospital but it was not on sale in the New York market
>
> You will probably have already heard from Messrs Schieffolin and Co with regard to the cassia
>
> I am desirous of obtaining some more of the fluid extract and I shall therefore be very much obliged to you for a further sample or for information regarding its purchase in New York
>
> The following is a short description of the results —
>
> Case 1 —H C aged 17 male Chills and pyrexia. April 10th 1902. Blood examination: Plasmodium malariæ, tertian parasite intracellular pigment. No quinine, administered cassia Beareana ʒvi 30 drops in water ev two hours no more chills no plasmodium on subsequent blood examination
>
> Cassia seemed to check nausea and vomiting
>
> Case 2.—J C aged 10 History of malarial fever in summer 1901 had first chill with severe headache and prostration on May 16th 1902. Blood examination: Pigmented crescentic forms and ring shaped bodies in all stages of development. No quinine cassia Beareana 15 drops ev 2 hours Has been doing well Did not return for further treatment. No second blood examination
>
> Case 3 —John C aged 40 m First attack May 16th 1902 Took quinine sulph gr viii on Friday May 16th had subsequent attack Cassia B ev 2 hours Took ʒi or a little more altogether No subsequent attacks
>
> Bl exam: May 16th 1902 Tertian parasite
> May 21st 1902 No organism
>
> From the meagre experience with the drug it is not legitimate for me to say that cassia B is a specific for all cases of malarial fever but it would seem that it has a special action on the organism and as far as my knowledge goes is not accompanied by any unpleasant symptoms

Although we cannot approve of the action of the lady from Ceylon in taking a new drug without medical assent, yet it would appear from the two communications which we have quoted that cassia Beareana is likely to prove of use in the treatment of more forms of malaria than one.

THE UNIVERSAL EXPOSITION OF ST LOUIS, 1904

THE Universal Exposition which will be held at St. Louis in 1904 will commemorate the acquisition by the United States in 1803 of the great territory then known as Louisiana but which now comprises the state of Louisiana and 11 other States The area of the territory is 1,000,000 square miles and Napoleon sold it to the United States not from any love of America but because he was engaged with various wars in Europe, and notably with England. The intent of the exhibition is, in the words of the official circular, "to form a roll of honour of man and the works of man in his industries and crafts." The Exposition will cover some 1200 acres and no charge will be made for space to exhibitors Cranes and hoists for handling heavy exhibits will also be provided free of charge and in addition all power necessary for the showing of machinery exhibits or for demonstrating processes will be supplied free. All exhibits from foreign countries will be admitted free and no exhibitor from a foreign country is to be held liable for the infringement of any United States trade-mark or patent "where the complaint is based upon the exhibition of any article or thing at the Exposition ' Among the various departments are those of education, social economy, art, the liberal arts, including the medical profession in some of its forms, manufactures, transport, agriculture, and anthropology Under the heading of agriculture are included preserved foods, wines, spirits, and fabrics It is intended that the juries for deciding on the excellence or otherwise of the exhibits shall be international. We earnestly hope that one section or portion of a section will be devoted to adulteration, substitution, or what are euphemistically called "trade terms ' For instance, what is called brandy is often made from beet or rice, Mocha coffee, although real coffee, comes from Jamaica, silk which *is in great part cotton, and so on We are only too* well aware that this sort of fraud is systematically practised in our own country and we have every reason to suspect that the same thing happens in other countries. Our contention is that any substance which is sold under one name but which contains a large proportion of another substance should be sold, not simply as a mixture, but should be labeled with a ticket showing the exact quantity of the different substances Take, for example, coffee, instead of saying, "This is sold as a mixture of chicory and coffee" the label should run, "This is a mixture of three parts of chicory"—or whatever the proportion may be—"to one part of coffee." An exhibition in which the various fraudulent processes were set out would do an enormous amount towards enabling the people either to get pure substances or at least to know what they are buying

COMPLAINTS have recently been made that some of the metropolitan water companies have raised their water rates and the suggestion has been made that this has been done in order that a larger sum may be given for compensation when the companies' undertakings are sold The *Times* of Jan. 9th contains the summary of a complaint by a gentleman who is supplied by the Southwark and Vauxhall Company It is not to our purpose to go into the merits of this or any other particular case, but it may possibly be of use for us again to point out that the Metropolis Water Act, 1897 provides facilities for the investigation of any cause of complaint not only in regard to the quantity or quality of the water supplied but also of the charges imposed by the companies (See report of THE LANCET Special Commission on the Metropolitan Water Supply, The Question of Control, THE LANCET, July 21st, 1900, pp 181–197)

The King has granted to Dr Percy Athelstan Nightingale His Majesty's Royal licence and authority to wear the Insignia of the Fourth Class of the Royal Siamese Order of the White Elephant, conferred upon him by His Majesty the King of Siam in recognition of valuable services rendered to the Government of Siam when acting as Siamese delegate to the International Medical Conference at Brussels

A dinner of the past and present students of the University of Durham College of Medicine will be held on Friday, Jan. 30th, at 7 P M, in the County Hotel Newcastle-upon Tyne when the chair will be occupied by Professor R Howden. Tickets, 7*s* 6*d* each, may be had nel Stevenson s transference to the Medical Staff College ondon would not entail a loss to the successful candi- s for the Indian Medical Service, for he would instruct the junior and senior classes at the college, so that valuable teaching and the influence he had so long and eficially exercised at Netley would still be exercised the good of both services. They were also very fortunate having Colonel Macleod as professor at Netley, he was o er of strength to the school to which he gave the eht ot his great teaching ability and long experience. y might also expect assistance for the teaching staff here, hat they had much to be thankful for and especially that Advisory Board for the Army Medical Services had lertaken the supervision of the course of instruction ried out at Netley and they might now hope that the ool would remain available for lieutenants of the Indian dical Service until a similar course could be provided else- ere. Many present could bear testimony to the great ue of the laboratory course which they had undergone in giene and pathology at the Staff College in London under direction of the Advisory Board as an important part of War Office reorganisation scheme. Those interested in the lian Medical Service considered it to be essential that the n who proceeded from Netley straight to service in India ould have the benefit of clinical instruction under skilled idance in the great hospital at Netley directly after the oratory course—whilst methods and processes were fresh the mind—for greater facilities and more clinical material tropical diseases were available there than elsewhere in United Kingdom Professor Macleod had kindly read a st gratifying report on the work of the class during the urse now closed and he heartily congratulated both the ofessors and the class on that report. Gentlemen (he ncluded) you will soon be called on to put to full e the valuable knowledge you have acquired during your rriculum and we shall watch your careers with much terest You have gained entrance to a grand service with eat traditions and made famous by many celebrated mes. I commend to your perusal a most interesting count by Surgeon General W B. Beatson, of "The Indian edical Service, Past and Present," first published in the *siatic Quarterly Review* for October last. In his paper rgeon General Beatson gives a history of the service, as r as it can be ascertained from the records which he arched, from its origin in the latter part of the sixteenth ntury, and he mentions most of the eminent men who ave contributed, up to a comparatively recent date to the me and renown of our grand service. Surgeon-General eatson concludes with the following well-deserved ibute —

> Since 1800 the Indian Medical Service has been completely re- ganised, and in many respects improved. Study of its past history veals how closely it has been associated with the foundation of the ritish Empire in India how great has been its influence in support g and developing it in harmonising differences and in reconciling to ritish rule the multitude of races and tribes which constitute the eople of India. It tells how much has been done by Indian medical ficers to increase our knowledge of Indian products and the evelopment of industries arising out of them how it has originated nd developed great departments of the public service.
>
> Indian medical officers have been largely concerned in bringing to erfection the post and telegraph systems the forest department. the anagement of gaols the system of State sanitation, and have held edical charge—executive and administrative of the military and ivil stations of India. They have helped to introduce the study of nglish literature and science into the scheme of native education in ndia.
>
> They originated the system of medical education which is now arried on in the Presidency towns and numerous other centres By eans of Indian officers a system of medical education has been stablished and has resulted in the formation of a class of well- ducated native medical practitioners and subordinate warrant medical fficers who administer the hospitals and dispensaries provided verywhere by a benevolent Government for the relief of the sick nd suffering

Surgeon-General Townsend thanked Sir William Hooper for coming to Netley to distribute the prizes and for his dmirable address, he said that he had that morning eceived a letter from Sir Joseph Fayrer which he should ike to read —

> Dear Surgeon-General Townsend —Pray accept my warm thanks or the kind invitation you have just sent me to attend the istribution of prizes at Netley on the 10th inst., and also my regret hat I am unable to avail myself of it
>
> For many years I have been a deeply interested attendant of these eetings and I rejoice to know that they are to continue. Having ong known what valuable services the Army Medical School has endered to my old and much loved service I am anxious to express to he candidates my warm gratification that the old meetings are to be ontinued and my earnest hope that the school will long continue to urnish able and competent officers as hitherto
>
> I regret my absence, necessitated by the state of my health which does not admit of my taking a long journey in winter the more that it deprives me of an opportunity of expressing as one of the oldest members of the Indian Medical Service, my congratulations to Sir William Hooper on the honour which has recently been bestowed on him, which is but a fitting acknowledgment of his services to the State, both in India and at home, as well as of his consistent and strenuous advocacy of the claims of the service which he adorns and which owes him so much for all he has done for it.
>
> Will you also convey my heartiest congratulations to the successful candidates and say how much I regret being absent on this interesting occasion, and offer them my best wishes for success in the noble service which they are now entering?
>
> Yours sincerely
> J Fayrer.

Surgeon General Townsend brought the proceedings to a conclusion by wishing the young officers God speed and every success in India. The company was subsequently entertained at luncheon by the officers of the Royal Army Medical Corps.

ASYLUM REPORTS

Gartloch Asylum, Glasgow (*Report for the year ended May 15th, 1902*) —The average number of patients resident during the year was 557 comprising 290 males and 277 females The admissions during the year amounted to 262—viz., 136 males and 126 females. Of these 174 were first admissions Dr W A Parker, the medical superintendent, states in his report that the most prolific immediate causes of insanity during the year were alcohol and syphilis. In 99 out of 262 admissions, or 37 per cent., there was a history of alcoholism and in 89 out of the 99 alcohol seemed to be the prime factor in the causation of the insanity The number of patients discharged as recovered during the year amounted to 107, comprising 60 males and 47 females or 18 9 per cent. of the average number resident. The deaths during the year were 52, or 9 2 per cent. as calculated on the same basis. Of the deaths three were due to renal disease, six each to senile decay and cerebral hæmorrhage, 10 to pulmonary and other forms of tuberculosis, 15 to general paralysis of the insane, and the rest to other causes A sanatorium for the isolation and treatment of consumptive patients was opened in the autumn of 1902. Four cases of serious fracture of bones occurred during the year, one of these being the fracture of a femur sustained by a patient in an attempt at suicide by jumping through a window For a short interval during the year the asylum had to be closed to visitors owing to the prevalence of small pox in Glasgow, but happily the precautions taken sufficed to keep the disease at bay The Commissioners in Lunacy state in their report that the asylum was found to be in excellent order, that the condition of the patients as a whole produced a favourable impression, and that the medical case-books and registers were carefully and well kept. The committee of management states in its report that plans for the enlargement of the asylum which had been accepted a year ago had been departed from in the meantime. Arrangements for increasing the lavatory accommodation in the official block of the asylum and at the mortuary have been made, and the drainage of the moss-land which forms part of the estate near the loch has been almost completed.

London County Asylum Colney Hatch (*Report for the year ended March 31st 1902*).—The average number of patients resident during the year was 2505, comprising 914 males and 1591 females. The admissions during the year amounted to 473—viz. 145 males and 328 females. Of these, 389 were first admissions. Dr W J Seward, the medical superintendent, states in his report that the admissions included 26 cases of epilepsy and 44 of general paralysis and that 25 per cent. of the patients admitted were stated to have shown a suicidal tendency before admission. With regard to the probable causes of insanity, hereditary tendencies were ascertained to exist in 25 per cent of the cases and in 5 per cent. there was congenital defect, 28 per cent. had been under treatment for previous attacks and 13 per cent were known to be of intemperate habits

The number of Jewish patients admitted during the year was 71, the great majority of whom were Russian Poles and at the present time there are 244 Jewish patients in the asylum.' The number of patients discharged as recovered during the year amounted to 194, comprising 41 males and 153 females, or 7 7 per cent. of the average number resident The deaths during the year amounted to 206—viz., 76 males and 130 females, or 8 2 per of these conditions are incurable If now we consider the general effect of the treatment of causes of illness which have already brought forth reactive symptoms of the body we shall see that in most cases the effects are illusory and only in very isolated cases effective On the other hand, in these latter cases the effect, as in malaria or acute polyarthritic rheumatism, is distinctly brilliant. The removal of established lesions must be left to the self defence of the organism itself both in acute and in chronic conditions. If this is not possible ease can only be procured by systematic treatment. When a condition of atrophia granularis renis cum hypertrophiâ cordis exists neither art nor knowledge will ever be able to enlarge the shrunken kidneys or to shrink the enlarged heart. An emphysematous lung can never be made to resume its normal condition, in the case of multiple insular sclerosis of the brain and spinal cord the sclerosed nerve can never be converted back into normal tissue. In many cases of organic disorders, established by an acute process, a better prospect of relief has been opened up by the serum treatment. But here also there must remain a large number of cases which are inaccessible both to the self-defence of the organism and to therapeutic measures Medical art and knowledge must ever be satisfied with this—the limits of the healing art end here

And are we to rest content with this state of affairs? Must we resign ourselves to it? No, indeed, for if now and in the future we are unable to cure the greater number of diseases when once they have developed, yet one other course remains for us to pursue—the prevention of the development of disease, the perfection of prophylactic measures. The furtherance of this ideal must be our aim. I am convinced that in no great length of time we shall attain this result, that as hygiene is now taught beside pharmacology so the special study of prophylaxis will be established. The dawn of this new phase of medical knowledge broke more than 100 years ago with the marvellous discovery of vaccination against small pox There followed upon this discovery a long period of inactivity, but it was the original pioneer who opened out the way for the principles of bacteriology If cholera and plague have lost much of their severity in their original homes we may thank prophylaxis for it. It is questionable whether we shall ever obtain a serum or an antitoxin capable of destroying the cholera or plague developed in India or other acute infectious diseases But without doubt there is now more certainty in protecting a country or an individual from the invasion of the seeds of disease. If this is the case with this class of disease, which includes acute and curable conditions, so much more can it be said of those conditions in the course of which absolutely irreparable changes are developed. In spite of many pharmacological attempts and other measures against tubercle, this most terrible disease can only be combated in one way—viz, by the protection from all infection. For such cases as contraction of the kidney or cirrhosis of the liver, and countless other diseases, no therapeutic principles but only prophylaxis are to be thought of. I will give no further examples, those that I have quoted will serve as illustrations

It is evident that you can only treat a disease when you know its character and its cause in order that the latter may then be avoided Our experience with acute infectious diseases is the certain proof of this. It follows that there must be a restless constant striving after the cause of disease and the recognition of these causes is the first step towards the fulfilment of the medical art of the future.

The proceedings of this Congress have given us another proof that in prophylaxis lies the hope of the future. Cholera, abscess of the liver, dysentery bilharziosis, and ankylostomiasis can only be combated by prophylaxis I fear that for many reasons the attainment of this ideal object will be postponed to the distant future. But it must be striven for and eventually it will be achieved. That in principle, at least, the work of us medical men should become unnecessary must be our constant striving, and to this end we must, to the best of our powers, assist.

Gentlemen, this brilliant Congress, with its fruitful and original work has now come to an end We strangers must leave this beautiful country which has been blessed by the culture of antiquity If in future years we should return here we shall see that the pregnant words of the Arab saying have come to pass "The Nile will come to the desert because the king was good." Then that which in its beginning promises such wonders will have grown to a more perfect blossoming, the noble spirit of my colleagues who are working here will have borne still finer fruit. And so may God bless the exalted ruler of this beautiful country and his people.

MEDICAL STAFF COLLEGE, NETLEY

THE second half of the first session of the Medical Staff College, held at the Royal Victoria Hospital, Netley, for lieutenants of the Indian Medical Service, was brought to a close on Jan. 10th, when the prizes were distributed by Surgeon General Sir William R. Hooper, K C S I., I M.S., President of the Medical Board at the India Office.

The proceedings commenced at 11 30 A.M in the presence of a large company, which included the principal medical officer of the hospital, Surgeon General E. Townsend, C.B., C M G, R.A M C, Colonel H Cayley, C M G, Dr A. E Wright (late professor of pathology), Colonel W F Stevenson, C B, R A.M C, Colonel Kenneth Macleod, I.M.S. (ret.) (professor of military and tropical medicine), Major W W Webb I.M S (ret), and the military and nursing staff of the Royal Victoria Hospital

Colonel Macleod read a report giving details of the work of the session, which extended over a period of two months.

The following list shows the results of the examination at Netley only —

INDIAN MEDICAL SERVICE.

List of lieutenants on probation of the Indian Medical Service who were successful at the Netley examination The prizes are awarded for marks gained in the special subjects taught at the Medical Staff College.

* Gained the Montefiore prize of 20 guineas and medal.
† Gained the second Montefiore prize
‡ Gained the Martin memorial medal
** Gained the Maclean prize for clinical and ward work

Sir WILLIAM HOOPER having handed the prizes to, and congratulated, the winners, delivered the following address which was listened to with great interest and received with repeated marks of approval He said that the four prizes which he had just had the honour of presenting formed the share, and a fair share, allotted to the lieutenants of the Indian Medical Service of the nine prizes formerly open to lieutenants of both the Royal Army Medical Corps and the Indian Medical Service, four being now competed for by lieutenants of the Royal Army Medical Corps on completion of the Medical Staff College course in London, whilst the ninth prize—that for hospital administration, presented by Mrs Marshall Webb in memory of the late Surgeon General William Marshall Webb—was open to officers of both services and was won this session by Lieutenant Mackenzie of the Royal Army Medical Corps. It was particularly gratifying to him to have the honour of presenting the prizes, for in July last, when Earl Roberts very kindly made the distribution at the Royal Victoria Hospital, it was feared that there would be no subsequent distribution there and that the War Office might even close the school in which under Parkes, Longmore, Maclean, Aitken, de Chaumont, Boyes-Smith, and more recently under Colonel Cayley, Colonel Notter Colonel Bruce, Colonel Macleod, Colonel Stevenson, and Professor Wright, a long list of men of both services had received most valuable instruction. Everybody would greatly regret that Professor Wright had severed his connexion with the Staff College—a teacher of great ability who possessed the gift of imparting to his hearers some of his own zeal and love for science Under him many members of both services had qualified for the valuable work they had since done. They must all feel thankful that

Looking Back.

SURGICAL LECTURES,

DELIVERED BY

MR. ABERNETHY

Theatre, St Bartholomew's Hospital

LECTURE 14[1]

Nervous Affections.

I say that there is a certain *disorder* of the nerves of the part antecedent to *disease* in the part. Suppose that there is disturbance in any part, you cannot say that it is disease, it begins with irritation, and therefore I object to the word disease in that sense. Functional disorder precedes any change in the structure of the part, but I believe it to be originally nervous. I say to persons who come to me with weakness of the muscles spasm, and irritation, occurring in any part of the body, that it is the result of something wrong in the nervous system as a whole. I could quote plenty of cases illustrating this, showing that local irritation and disease are the effect of something wrong in the nervous system. This is very well exemplified in the complaints which attend dentition in children, where the nervous irritation sometimes disorders all the parts of the body, there are convulsions, weakness of the muscles, the arms are turned out and sometimes inwards and so on. The larynx also becomes affected, and all persons lose their voices all of a sudden, all through an affection of the nerves of the part.

Then again the nerves of a part may be influenced by something operating on the trunks of the nerves leading to those parts, as in injuries or affections of the spinal column, all the nerves in the parts supplied from below the part of the medulla spinalis injured, will be deprived of their vitality Again, affections of the nerves of the cerebrum may produce local affections in every part of the body We cannot conceive disease to be merely local, there must always be a plurality of parts affected. The subject is one difficult to explain, but what I want chiefly to call your attention to is, a very painful affection of the nerves of a part called *Tic Doloreux* It was a rare thing, in the early part of my life, to see many cases of disease produced by increased vascular action, which are now common, and so it is with diseases depending on an undue nervous action in a part, for I do not think there was such a thing as *tic doloreux* ever dreamt of in my time. How this comes, I don t know

---

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 9164 births and 5350 deaths were registered during the week ending Jan. 10th. The annual rate of mortality in these towns which had been 19 6, 16 9 and 20 0 per 1000 in the three preceding weeks, declined again last week to 18 5 per 1000 In London the death rate was 18 8 per 1000 while it averaged 18 4 in the 75 other large towns. The lowest death rates in these towns were 10 0 in Hornsey 10 9 in Handsworth and in West Hartlepool, 11 8 in Walthamstow 12 3 in Southampton 12 4 in York, and 12 7 in Leyton, the highest rates were 21 7 in Manchester 22 7 in West Bromwich and in Rochdale, 23 7 in Liverpool 22 4 in Wolverhampton 24 4 in Rhondda 25 2 in Oldham, and 58 2 in Great Yarmouth The 5350 deaths in these towns last week included 504 which were referred to the principal infectious diseases, against 620, 493, and 603 in the three preceding weeks, of these 504 deaths 136 resulted from measles, 132 from whooping cough, 73 from diphtheria, 65 from scarlet fever, 50 from diarrhœa, 38 from "fever" (principally enteric) and 10 from small pox. No death from any of these diseases was registered last week in Hornsey, Bournemouth, Reading Norwich, Burton on-Trent, Bootle, Warrington, Barrow in-Furness, Huddersfield, Halifax, York, or Stockton-on Tees, while the highest death rates from the principal infectious diseases were recorded in West Ham, Hastings, Smethwick, Liverpool, St. Helens, Tynemouth, Newport (Mon), and Cardiff. The greatest proportional mortality from measles occurred in Hastings Devonport, Walsall, Liverpool, Salford, Tynemouth, Newport (Mon.), and Cardiff, from scarlet fever in Great Yarmouth, King s Norton, Coventry, and St. Helens, from diphtheria in Hastings, Hanley, Smethwick, Bury and Preston, from whooping cough in Tottenham, West Ham, Oldham, and Cardiff, and from diarrhœa in Wolverhampton. The mortality from "fever" showed no marked excess in any of the large towns. Of the 10 fatal cases of small pox in these towns six were registered in Liverpool and one each in London, Derby, Oldham, and Preston The Metropolitan Asylums hospitals contained 10 small-pox patients on Saturday, Jan 10th, against 21, 17, and 14 on the three preceding Saturdays, four new cases were admitted during last week, against five, none, and one in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2487, 2523, and 2378 at the end of the three preceding weeks, had further declined to 2219 at the end of last week, 223 new cases were admitted during the week, against 279, 205, and 214 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London which had been 408 343, and 415 in the three preceding weeks, declined again last week to 354, and were 203 below the corrected average number Influenza was returned as the primary cause of 39 deaths in London last week, against 37 28, and 37 in the three preceding weeks The causes of 74, or 1 4 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner The causes of all the deaths were certified in West Ham, Bristol, Leicester, Salford, Leeds, Newcastle-on-Tyne, and 42 other smaller towns, the largest proportions of uncertified deaths were registered in Hanley, Birmingham, Smethwick, Liverpool, Warrington, Sheffield, and Sunderland

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21 1, 21 3, and 21 6 per 1000 in the three preceding weeks, further rose to 22 6 per 1000 during the week ending Jan. 10th, and was 3 8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17 0 in Perth and 17 3 in Greenock to 24 2 in Leith and 24 4 in Glasgow The 740 deaths in these towns included 24 which were referred to whooping cough, 22 to diarrhœa, 15 to measles, seven to diphtheria, seven to "fever, and three to scarlet fever, but not one to small-pox. In all 78 deaths resulted from these principal infectious diseases last week, against 68 59, and 77 in the three preceding weeks. These 73 deaths were equal to an annual rate of 2 4 per 1000, which was 0 8 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 20 and 33 in the two preceding weeks declined again last week to 24, of which 17 were registered in Glasgow, two in Edinburgh and two in Dundee. The deaths from diarrhœa, which had been 18 and 14 in the two preceding weeks rose again to 22 last week, and included 14 in Glasgow two in Edinburgh two in Aberdeen and two in Greenock The fatal cases of measles, which had been five, six, and 10 in the three preceding weeks, further increased last week to 15, of which 10 occurred in Aberdeen, two in Glasgow, and two in Edinburgh. The deaths from diphtheria, which had been four six, and 13 in the three preceding weeks, declined again to seven last week, and included three in Glasgow, two in Edinburgh, and two in Dundee The fatal cases of 'fever," which had been six, six, and four in the three preceding weeks, rose again last week to seven of which four were recorded in Glasgow The three deaths from scarlet fever corresponded with the cent as calculated on the same basis. Of the deaths, nine were due to pneumonia, 10 to cardiac disease, 14 each to epilepsy and senile decay, 26 to colitis, 29 to pulmonary tuberculosis, 36 to general paralysis of the insane, and the rest to other causes There has been a considerable amount of serious illness on the female side of the asylum during the year, including cases of enteric fever, scarlet fever, and colitis. The Commissioners in Lunacy state in their report that the patients were found remarkably tranquil and on the whole contented, that many of the wards were improved as regards their lighting and ventilation, and that the medical case books and pathological records were well kept. The committee of management states in its report that plans have been prepared and approved by the Home Secretary for the erection of an isolation hospital, and for this purpose a sum of £2000 has been voted. The farm shows a profit of £652 for the year The expenditure on repairs has amounted to £8270 5s during the year, while the sum of £281 has been expended on additions, alterations, and improvements

THE BLOODLESS REDUCTION OF DISLOCATION OF THE HIP

A DEMONSTRATION BY PROFESSOR LORENZ

PROFESSOR A. LORENZ of Vienna demonstrated on Jan. 14th at the City Orthopædic Hospital, Hatton garden, London, E C, his bloodless method of reducing congenital displacement of the hip He performed the operation on two cases, one being a case of bilateral congenital displacement of the femora and the other a unilateral displacement. This was followed by a demonstration of the method adopted in the treatment of congenital club-foot. He was aided by his assistant, Dr Friedrich Müller, Mr J, Jackson Clarke, Mr John Poland, and Mr Noble Smith, and an audience of over 90 medical men watched his procedure His remarks, which he gave in English, were frequently received with applause and his reception was altogether of a most cordial character

The proceedings were opened by Mr NOBLE SMITH introducing Professor Lorenz to the meeting in a short speech in which he said that though a distinct expression of opinion adverse to the operation advocated by Professor Lorenz had been definitely put forward at the Clinical Society of London quite recently, still it was the custom in England to give everyone a fair field and no favour and that was all that Professor Lorenz wished for

Professor LORENZ while he was operating said he was glad to take advantage of the occasion to communicate theoretically and practically one of his bloodless methods. The most important of these methods was the treatment of congenital hip dislocation by what he called "the functional weight-bearing method" The first step in the treatment was to place the head of the femur into the acetabulum. The possibility of this reduction was limited by the age of the patient In very young children of course, there would never be any difficulty in pulling down the head to the right place, in older children or in adults there was less possibility of doing so To accomplish the reduction all soft parts, in particular the long muscles, must be stretched, and, if necessary, torn, so as to overcome their resistance. The adductors showed the greatest resistance. The anterior muscles offered a great resistance which must be overcome by traction and in case of necessity by over extension The posterior muscles offered less resistance which could be considerably lessened by bending the knee It became possible by these manipulations to pull down the femoral head so as to bring it opposite the acetabulum and thus the preparatory steps of the treatment were finished The real reduction—i e, the placing of the head into the acetabulum—could be done by traction and by bringing pressure to bear on the trochanter He preferred the reduction by forced abduction which was kept up until the well known signs of the slipping of the head over the posterior border of the acetabulum could be felt If the acetabulum were of normal shape and size the leg could be brought down to its normal position without any further delay But as in these cases the acetabulum was of subnormal size the head would slip out of it immediately after the leg was brought into even an approximately normal position In order to retain the head in its place it was necessary to put the leg in the position of right-angled abduction In case of great instability of the replaced head, to the abduction a slight hyper-extension had to be added. In order to add to the security of fixation of the head in the acetabulum it was expedient to stretch and to enlarge the anterior part of the capsule by rotary movements of the thigh In the new position all the flexors of the knee-joint were too short so that there was rigid flexion of the knee. This was a symptom which indicated the completeness of the reduction. This contracture must be corrected by stretching while the patient was still under the anæsthetic. The extreme abducted position of the leg must be fixed by a plaster of Paris cast which, in order to present all the details, was applied in the presence of his audience Continuing, Professor Lorenz said that his routine was to leave the plaster of-Paris cast undisturbed for six months at least, sometimes for even longer Of course, he took all necessary precautions to keep the skin under the cast in a healthy condition. The cast was applied over knitted drawers, underneath which a three inch calico band ran, protruding at both ends By pulling this band in different directions a regular rub down was administered. His principle guiding the after treatment, after the cast was removed, was to keep the head of the femur pressed against the acetabulum. He did not try to correct the position of the legs in any hurry but allowed only so much reduction of the extreme abduction as was indispensable for letting the child get about with spread legs during the day At night the primary extreme abduction was reinstituted, for this purpose a wedge shaped cushion was adjusted between the legs and fastened there, the patient being in the recumbent position. Another important feature of the after treatment was appropriate gymnastic exercise, which mainly consisted in passive and active flexions of the hip in order to procure mobility. Professor Lorenz thought that next to congenital dislocation of the hip-joint the most frequent congenital deformity was congenital club-foot. The treatment of this deformity in the newly born was almost uniformly a bloodless one and he advocated his "bloodless modelling method" as one which thoroughly cured the deformity in the newly born, so that a bloody operation in the more advanced age did not become necessary In explaining this method he said it consisted, firstly, in overcoming the shortening of the soft parts whatever they might be—i.e., the skin, the subcutaneous tissue, the tendons, the fascia, and the ligaments. It was very important not only to overcome the resistance of these shortened soft parts, but this resistance had also to be practically annihilated. By merely correcting the deformity the soft parts were stretched, but their elasticity would counteract the correction and as soon as the foot was let go it would return to the wrong position. If at this stage of affairs the foot were retained in its corrected position by any appliances, casts, or splints there would be painful sores on the points most exposed to pressure The principle of his modelling was to keep on with the single acts of correction until the elasticity of the tissues was completely destroyed so that the foot rebounded no more into its previous wrong shape The foot must become "as pliable as a piece of [illegible] cloth" In this state he could mould it in almost any shape and it would stay there without any tendency to return to the previous position. As to the special technique, it was entirely erroneous to try to redress the deformity, so to say, in its bulk The deformity must be divided into its component parts and be overcome in a certain order. First came the correction of the faulty adduction, then the straightening out of the extreme inflection over the instep, then the equinus position had to be attacked, and then the supination. After this gradual correction was accomplished the complete reduction of the deformity *in toto* was feasible. The cast might now be applied without any danger of pressure and its sequelæ. It must be kept in mind that by this rather forcible treatment slight disturbances of the circulation were caused, so that a swelling of the limb resulted This circumstance necessitated the following precautions. Any cast applied must be fenestrated so that it was possible to keep the condition of the foot under permanent and full control It was his principle to make sure that the circulation in the extreme tips of the toes was perfect before dismissing the child with its cast. The cast could be kept on the foot for several months and renewed after removal until the foot was in complete valgus position even after being freed from all dressings Then gymnastic exercises and massage should be resorted to, the aim being to develop and to strengthen the pronators so that the valgus position was maintained by the tonicity of these muscles.

Looking Back.

LECTURE 14[1]

Nervous Affections

I say that there is a certain *disorder* of the nerves of the art antecedent to *disease* in the part. Suppose that there is isturbance in any part, you cannot say that it is disease, begins with irritation, and therefore I object to the word isease in that sense Functional disorder precedes any hange in the structure of the part, but I believe it to e originally nervous. I say to persons who come to me ith weakness of the muscles, spasm, and irritation, occurring n any part of the body, that it is the result of something rong in the nervous system as a whole. I could quote lenty of cases illustrating this, showing that local irritation nd disease are the effect of something wrong in the nervous ystem. This is very well exemplified in the complaints hich attend dentition in children, where the nervous ritation sometimes disorders all the parts of the body, there re convulsions, weakness of the muscles, the arms are urned out and sometimes inwards, and so on. The larynx lso becomes affected, and ah! persons lose their voices all f a sudden, all through an affection of the nerves of the art.

Then again the nerves of a part may be influenced by omething operating on the trunks of the nerves leading to hose parts, as in injuries or affections of the spinal column, ll the nerves in the parts supplied from below the part f the medulla spinalis injured, will be deprived of their itality Again affections of the nerves of the cerebrum ay produce local affections in every part of the body We annot conceive disease to be merely local, there must lways be a plurality of parts affected. The subject is one ifficult to explain, but what I want chiefly to call your ttention to is, a very painful affection of the nerves of a art called *Tic Doloreux* It was a rare thing, in the early art of my life, to see many cases of disease produced by ncreased vascular action which are now common, and so t is with diseases depending on an undue nervous action in part, for I do not think there was such a thing as *tic oloreux* ever dreamt of in my time. How this comes, I on't know

---

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 9164 births and 5350 eaths were registered during the week ending Jan. 10th. The annual rate of mortality in these towns, which had een 19 6, 16 9 and 20 0 per 1000 in the three preceding weeks, declined again last week to 18 5 per 1000 In London the death rate was 18 8 per 1000 while it averaged 18 4 in the 75 other large towns. The lowest death rates in these towns were 10 0 in Hornsey 10 9 in Handsworth and in West Hartlepool 11 8 in Walthamstow 12 3 in Southampton, 12 4 in York and 12 7 in Leyton, the highest rates were 21 7 in Manchester, 22 7 in West Bromwich and in Rochdale, 23 7 in Liverpool 22 4 in Wolverhampton 24 4 in Rhondda, 25 2 in Oldham and 58 2 in Great Yarmouth The 5350 deaths in these towns last week in ded 504 which were referred to the principal infectious diseases, against 620, 493, and 603 in the three preceding weeks, of these 504 deaths 136 resulted from measles, 132 from whooping cough, 73 from diphtheria, 65 from scarlet fever, 50 from diarrhœa, 38 from "fever" (principally enteric) and 10 from small pox. No death from any of these diseases was registered last week in Hornsey, Bournemouth, Reading, Norwich, Burton on Trent, Bootle, Warrington, Barrow in Furness, Huddersfield, Halifax, York, or Stockton on Tees, while the highest death rates from the principal infectious diseases were recorded in West Ham, Hastings, Smethwick, Liverpool, St. Helens, Tynemouth, Newport (Mon), and Cardiff. The greatest proportional mortality from measles occurred in Hastings, Devonport, Walsall, Liverpool, Salford, Tynemouth, Newport (Mon), and Cardiff, from scarlet fever in Great Yarmouth, King s Norton, Coventry, and St. Helens, from diphtheria in Hastings, Hanley, Smethwick, Bury, and Preston, from whooping cough in Tottenham, West Ham, Oldham, and Cardiff, and from diarrhœa in Wolverhampton. The mortality from "fever" showed no marked excess in any of the large towns. Of the 10 fatal cases of small pox in these towns six were registered in Liverpool and one each in London, Derby, Oldham, and Preston The Metropolitan Asylums hospitals contained 10 small pox patients on Saturday, Jan 10th, against 21, 17, and 14 on the three preceding Saturdays, four new cases were admitted during last week, against five, none, and one in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2487, 2528, and 2378 at the end of the three preceding weeks, had further declined to 2219 at the end of last week, 223 new cases were admitted during the week, against 279, 205, and 214 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London which had been 408 343, and 415 in the three preceding weeks, declined again last week to 354, and were 203 below the corrected average number Influenza was returned as the primary cause of 39 deaths in London last week, against 37 28, and 37 in the three preceding weeks The causes of 74, or 1 4 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner The causes of all the deaths were certified in West Ham, Bristol, Leicester, Salford, Leeds, Newcastle-on-Tyne, and 42 other smaller towns, the largest proportions of uncertified deaths were registered in Hanley, Birmingham, Smethwick, Liverpool, Warrington, Sheffield, and Sunderland

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21 1, 21 3, and 21 6 per 1000 in the three preceding weeks, further rose to 22 6 per 1000 during the week ending Jan. 10th, and was 3 8 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17 0 in Perth and 17 3 in Greenock to 24 2 in Leith and 24 4 in Glasgow The 740 deaths in these towns included 24 which were referred to whooping cough, 22 to diarrhœa, 15 to measles, seven to diphtheria, seven to "fever," and three to scarlet fever, but not one to small pox. In all 78 deaths resulted from these principal infectious diseases last week, against 68 59, and 77 in the three preceding weeks. These 73 deaths were equal to an annual rate of 2 4 per 1000 which was 0 8 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough, which had been 20 and 33 in the two preceding weeks, declined again last week to 24, of which 17 were registered in Glasgow, two in Edinburgh and two in Dundee. The deaths from diarrhœa, which had been 18 and 14 in the two preceding weeks, rose again to 22 last week, and included 14 in Glasgow, two in Edinburgh two in Aberdeen, and two in Greenock The fatal cases of measles, which had been five, six, and 10 in the three preceding weeks, further increased last week to 15, of which 10 occurred in Aberdeen, two in Glasgow, and two in Edinburgh The deaths from diphtheria which had been four, six, and 13 in the three preceding weeks, declined again to seven last week, and included three in Glasgow, two in Edinburgh and two in Dundee The fatal cases of "fever," which had been six, six, and four in the three preceding weeks rose again last week to seven, of which four were recorded in Glasgow The three deaths from scarlet fever corresponded with the number in each of the two preceding weeks and included two in Paisley The deaths referred to diseases of the respiratory organs in these towns which had been 193 and 158 in the two preceding weeks, further declined last week to 152, but slightly exceeded the number in the corresponding period of last year The causes of 31, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 30 8, 24 6, and 29 4 per 1000 in the three preceding weeks, declined again to 26 8 per 1000 during the week ending Jan. 10th During the past four weeks the death rate has averaged 27 7 per 1000, the rates during the same period being 19 0 in London and 19 8 in Edinburgh. The 195 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 19 from the number in the preceding week, and included 14 which were referred to the principal infectious diseases, against 20, 21, and 23 in the three preceding weeks , of these, three resulted from diphtheria, three from diarrhœa, two from measles two from scarlet fever, two from whooping cough, and two from "fever" These 14 deaths were equal to an annual rate of 1 9 per 1000, the death rates last week from the same diseases being 1 7 in London and 1 4 in Edinburgh The fatal cases of measles, which had been nine, seven, and nine in the three preceding weeks, declined again last week to three. The deaths from diarrhœa, which had been three, four, and three in the three preceding weeks, were again three last week. The mortality both from scarlet fever and from diphtheria showed a decline from that recorded in the preceding week The 195 deaths in Dublin last week included 37 of children under one year of age and 57 of persons aged 60 years and upwards , the deaths of infants and those of elderly persons corresponded with the respective numbers in the preceding week Six inquest cases and six deaths from violence were registered, and 62, or nearly a third, of the deaths occurred in public institutions The causes of 19, or nearly 10 per cent., of the deaths in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING DECEMBER, 1902.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of cases reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 7 4 per 1000 of the population, estimated at 4,579,107 persons in the middle of last year In the three preceding months the rates had been 9 1, 10 0, and 9 1 per 1000 respectively The rates were considerably below the average in Paddington, Kensington, Chelsea, Stoke Newington, the City of London and Shoreditch, while they showed the largest excess in Hackney, Southwark, Battersea, Wandsworth Deptford, and Lewisham The prevalence of small pox showed a slight decline from that recorded in the preceding month , of the 12 cases notified during December four belonged to Islington, two to Fulham, two to Hackney, two to Finsbury, one to Stepney, and one to Poplar The Metropolitan Asylums hospitals contained 14 small pox patients at the end of last month, against 42, 19, and 17 at the end of the three preceding months , the weekly admissions averaged three, having also been three in each of the two preceding months. Scarlet fever was considerably less prevalent during December than in either of the two preceding months , this disease showed the highest proportional prevalence in St. Pancras, Hackney, Lambeth, Battersea, Wandsworth, Deptford, and Lewisham The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2656 2820, and 2705 at the end of the three preceding months, had further declined to 2327 at the end of last month , the weekly admissions averaged 236, against 327, 358, and 301 in the three preceding months. The prevalence of diphtheria showed a slight decline from that recorded during November last , among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Hackney, Wandsworth, Lewisham, and Woolwich There were 927 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of December, against 961, 941, and 1019 at the end of the three preceding months, the weekly admissions averaged 136 last month, against 142, 149, and 157 in the three preceding months. Enteric fever showed a considerably diminished prevalence last month as compared with recent months, the greatest proportional prevalence of this disease occurred in Kensington, Finsbury, Shoreditch, Stepney, and Wandsworth The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 359, 401, and 339 at the end of the three preceding months, had further declined to 210 at the end of December, the weekly admissions averaged 30 last month, against 63, 59, and 37 in the three preceding months Erysipelas was proportionally most prevalent in St. Marylebone, Holborn, Bethnal Green Southwark, Camberwell, and Greenwich. The 33 cases of puerperal fever notified during the month included four in Wandsworth, three each in Battersea, Lambeth, and Camberwell and two each in St. Marylebone, Islington, Hackney, Stepney, and Woolwich

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the various boroughs in which the deceased persons had previously resided. During the five weeks ending Jan. 3rd the deaths of 7974 persons belonging to London were registered, equal to an annual rate of 18 2 per 1000 living, against 16 4, 16 0, and 17 4 per 1000 in the three preceding months. The lowest death rates last month in the several metropolitan boroughs were 11 7 in Hampstead, 14 1 in Stoke Newington, 14 4 in Paddington 14 7 in Hackney 14 9 in Woolwich, and 15 1 in Wandsworth , the highest rates were 20 7 in Bermondsey, 20 8 in Stepney, 21 0 in Poplar, 21 9 in Holborn 22 0 in the City of London, and 25 4 in Finsbury The 7974 deaths from all causes included 764 which were referred to the principal infectious diseases , of these, 261 resulted from measles 52 from scarlet fever, 116 from diphtheria, 204 from whooping cough, 55 from enteric fever, one from simple continued fever, 75 from diarrhœa, and not one from small pox or typhus The lowest death rates from these diseases were recorded in Kensington, Hampstead, Stoke Newington, Holborn, and Woolwich , and the highest rates in Fulham, St. Pancras, Finsbury, Stepney, Bermondsey, and Deptford The 261 fatal cases of measles were 28 below the corrected average number, among the various metropolitan boroughs this disease showed the highest proportional mortality in St. Pancras, Stepney, Bermondsey Camberwell, Deptford, Greenwich, and Lewisham. The 52 deaths from scarlet fever showed a decline of 32 from the number in the corresponding periods of the ten preceding years , this disease was proportionally most fatal in Islington, Hackney, Bethnal Green, Lambeth, and Deptford. The 116 fatal cases of diphtheria were less than one half of the corrected average number , among the various metropolitan boroughs this disease showed the greatest proportional mortality in Fulham, Chelsea, St. Marylebone, St. Pancras, Southwark, and Lewisham. The 204 deaths from whooping cough were 39 in excess of the average number in the corresponding periods of the ten preceding years. This disease was proportionally most fatal in Fulham, City of Westminster, St. Marylebone, Islington, Finsbury, and the City of London The 56 fatal cases of "fever" showed a decline of 34 from the corrected average number , among the various metropolitan boroughs the highest "fever" death rates were recorded in Kensington, St. Pancras, Islington Hackney, Lambeth, and Camberwell. The 75 deaths from diarrhœa slightly exceded the number in the corresponding periods of the ten preceding years , this disease was proportionally most fatal in Fulham, Chelsea, Stoke Newington Holborn, and Southwark In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was more than 22 per cent. below the average.

Infant mortality in London during December, measured by the proportion of deaths among children under one year of age to registered births, was equal to 155 per 1000. The lowest rates of infant mortality were recorded in Kensington, St. Marylebone, Hampstead, Hackney, the City of London, and Shoreditch , while the highest rates occurred in Chelsea, City of Westminster, Finsbury, Camberwell, Deptford, Greenwich, and Lewisham

VITAL STATISTICS OF LONDON DURING DECEMBER, 1902.

(Specially compiled for THE LANCET *)*

CITIES AND BOROUGHS.	Estimated population in the middle of 1902.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES											Deaths from all causes.	Death rate per 1000 living	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever	Diphtheria *	Typhus fever	Enteric fever	Other continued fevers.	Puerperal fever	Erysipelas	Cholera.	Total.	Annual rate per 1000 persons living	Small pox. * Including membranous croup

that the urine from two cases of tuberculosis of the bladder and diabetes respectively had many points in common probably resides in the fact that the subjects of the disease in question are either constitutional "hyperacids" or the subjects of retarded nutrition—Bouchard's "ralentis." In the first case the low specific gravity, the rising chlorides, and the pale colour of the urine indicate amongst other signs that the defences of the organism are breaking down and that the tuberculous affection of the bladder of twelve months' standing is threatening to become generalised. The organism, as Dr Gilchrist says, is becoming demineralised the chlorides now following an earlier excessive excretion of phosphates The supposition that this specimen of urine is taken from the subject of a gouty or atonic scrofulous diathesis, where such a resistance to infection is likely to occur, is rendered probable by the low figure of the phosphates (0 84 gramme) given by Mr Clayton. If here the solid residue is calculated by densimetry, as Dr Gilchrist did in his paper, the proportion of phosphoric acid stands at 1 in 33, precisely the same proportion is also found by taking the average of the three specimens of Mr Clayton's case of glycosuria. It would be instructive to know the diet prescribed in this case of glycosuria, the relatively high urea and phosphates found in specimen C lead to the conclusion that meat was a liberal item in the patient's dietetic treatment.

Judging by Dr S Vere Pearson's[3] and Mr A. W Pereira's[4] clinical observations on the apparent uselessness of urea in the treatment of tuberculosis, Dr Gilchrist's theoretical objections seem to be justified. Concerning the one point on which Dr H Harper and Dr Gilchrist agree with most modern opinion—that is, on the necessity for a highly nitrogenous diet in the treatment and prophylaxis of tuberculosis —I should feel inclined to follow the suggestion of Dr Gautrelet and to draw the supply of nitrogen at intervals from the leguminous plants, we know in fact that peas and lentils contain more nitrogen than meat in the proportion of about 46 to 42. I am, Sirs, yours faithfully,

J O B STATHAM,
Captain R.A M C

SIR THOMAS BROWNE'S EVENING HYMN

To the Editors of THE LANCET

SIRS,—In THE LANCET of Dec 20th, 1902, p 1702, the reviewer of a new edition of the "Religio Medici" states that he cannot call to mind any editor who has pointed out the similarity between Bishop Ken's Evening Hymn and the dormitive which Sir Thomas says he took "to bedward" In Gardiner's edition (1845) there is the following note 'Compare this with the beautiful and well known 'Evening Hymn' of Bishop Ken, and these again with several of the Hymni Ecclesiæ, especially that beginning 'Salvator Mundi, Domine,' with which Ken and Browne, both Wyckhamists, must have been familiar"

I am, Sirs, yours faithfully,

Baltimore Jan. 2nd 1903
WM OSLER.

THE DISCHARGE OF LARVÆ FROM THE STOMACH

To the Editors of THE LANCET

SIRS —The references in THE LANCET of Sept. 27th (p 891) and Nov 29th (p 1487), 1902 to the vomiting of the larvæ of dipterous insects, remind me that in the summer of 1900 I met with such a case. This was of an infant in arms, fed by the bottle who was said to have vomited maggots. The mother was directed to preserve the maggots if the vomiting was repeated, and some days afterwards a cluster of about 35 or 40 larvæ was produced. These were alive and being placed in water lived till the next day They were 'club shaped," tapering regularly from head to tail, and measured from four to eight millimetres in length, one was much longer, being about 11 millimetres. They had distinct red eyes A number were sent to the Clinical Research Association, which said it was unable to identify them. It was necessary to take the mother's word that they were actually vomited by the infant, but there could be no reasonable doubt about it. They were only noticed twice and were probably not sought for in the motions Beyond some slight gastro intestinal disturbance common in bottle fed infants in summer, there was little the matter with the child —I am, Sirs, yours faithfully,

Edgeworthstown
J F KEENAN, M.B. R.U.I.

RIGHT-HANDEDNESS AND LEFT BRAINEDNESS

To the Editors of THE LANCET

SIRS,—With all due deference to a master in science like Sir Samuel Wilks I would like to observe that in this, as with many other rather obscure physico mental acts, we should never lose sight of the three great fundamental modes and methods of reflex cerebral activity—reason, sensation, and will. Sensation inclines us to adopt modes of action most agreeable to the present comfort and pleasure of the individual, reason suggests what ought to be the mode, and will, or more properly speaking volition (for I suppose there must be a faculty of this nature), determines what the mode shall be The determination of a preferential right handedness is one of these modes due to a cerebro-spinal *functional* activity A subject of this kind, not easily susceptible of scientific demonstration, is very apt to make one drift into a form of physiological transcendentalism, but what I mean to urge is that there is no satisfactory and decided clinical evidence that right handedness has a structural foundation but that all such manifestations depend on outside influences acting on the brain centres—the combined result of education and necessity Let it be understood, however, that that centre is not preferential but a centre common to both the left and right side of the system How otherwise explain the philosophy of habit and, indeed, of many of the well recognised instincts of our nature? That the left hand should by no means hold a subservient position in reference to the right may readily be accepted if we consider the dual functional activity as seen in many handicrafts. In the days of a less exalted civilisation, before steam was so universally accepted as the great motor power, I have watched with interest and admiration the deftness with which the hand loom weaver used both hands in his daily occupation. His was an ambidexterity illustrating not only the aristocratic position of the left hand but the fact of left-handedness being not only a possibility—a desideratum—but a necessity of his workaday existence No one can deny that right-handedness is *preferential* and, indeed, almost a physical necessity because it appeals to the present, and often urgent, necessities of the individual. Left-handedness is *potential* and takes the position of a *reserve* force, a power which can be called into action under conditions of necessity when the other is in abeyance. This is all I claim for it. As Sir Samuel Wilks observes in his criticism, man is a two sided animal with an inequality as to functional power on one side as compared with the other. No doubt about this, but like many functional processes under the direct dominion of brain man's nature is amenable to outside influences and the conditions, as before remarked, of his environment. He can adapt himself to circumstances and make his left hand serve his needs if the right cannot. Hence education, hence training of children, hence the necessity of what we know as professional teaching—in short, of any kind or description of cult whatever Apologising for the length and prosiness of this letter I trust that though I may, like Mr Kipling's orang outang "Bimi," seem to have "too much ego in my cosmos," you will give me credit for the desire to give an all important point like this all the careful consideration it deserves.

I am Sirs, yours faithfully,

Rothwell Northamptonshire
JAMES MORE, M D Edin.

INTRAVASCULAR ANTISEPSIS

To the Editors of THE LANCET

SIRS,—Due importance will be attached by clinical observers to the results published in THE LANCET of Jan. 10th, p 98, of Dr J M. Fortescue Brickdale's able investigations into the subject of intravenous antisepsis, which conclusively demonstrate the inefficacy for direct germicidal purposes of our antiseptics of the day, used in the shape of intravenous injections Intravenous medication, however, is a distinct and much wider subject to which it may be premature to apply the same sweeping conclusions. Indeed, the proof that the injections are inert as germicides favours the impression, which for my part I have long entertained, that their beneficial effects are due to some other mode of action which it would be important to investigate and opens up the question as to the nature and the range of their usefulness. Internal therapeutics have not yet been reduced to the exclusive administration of antiseptics only, and if other remedies are still worth administering by the mouth for the treatment of intravascular conditions such as atheroma, aneurysm, endocarditis, and blood diseases in general, it may not be unreasonable to keep an open mind as to the possible advantages of the shorter route. This also applies to the treatment of pulmonary affections, because of the directness of the road of access. In the case of acute pneumonia the effects I have obtained with injections of protargol have appeared to me to be sufficiently striking to deserve further consideration from the pathological, as well as from the clinical, standpoint. I am not prepared to say whether the rapid reduction in temperature and the manifest general improvement in the clinical condition of the patients were due to the minute dose of protargol (from one half to one grain) or to the bulk (from 20 to 40 cubic centimetres) of the saline solution injected. Possibly the normal saline solution alone might have acted as well. At any rate the successful employment of collargol in two cases of pneumonia has quite recently been reported by M. R. Moutard Martin and M. P Thaon,[1] and at the same meeting M. Netter[2] referred to his successful treatment of a very bad case of infective endocarditis by the same agent The discovery of better remedies than the salts of silver may be hoped for in the future, but the results hitherto obtained with the help of the latter indicate that our study of the intravenous method should not be considered as closed but as barely opened as yet. I would be the last to advocate the indiscriminate use of this form of treatment I have myself often refrained from using it because I consider that it should not be undertaken except by skilful and highly-trained operators. The procedure is difficult and not free from anxiety These are also the limitations inherent to most of our life-saving surgical operations, but they have not been urged as arguments for depriving us of the benefit attaching to the risk.

THE THORNTON HEATH SLATE CLUB AND DR W B ADDISON

To the Editors of THE LANCET

SIRS,—By the kindness of a fellow practitioner my attention has been drawn to a paragraph in THE LANCET of Jan. 10th p 143 coupling my name with the word ' advertisement.' I enclose a letter from the secretary of the North Croydon Benefit Society showing that I was completely ignorant of the existence of the handbills you mention. I knew nothing of them , the possibility of the existence of such things had never even entered my mind. I have now severed my connexion with the club, which contains only 53 members, and is the only club appointment I have held during the seven years I have been in practice here By putting the word Advertisement" over your paragraph you distinctly accuse me of advertising As I knew nothing of the handbills it is obvious that I have not been advertising and it is equally obvious that it is a scandalous thing that I should be accused by a paper of the supposed high standing of THE LANCET of doing a disgraceful act without a shred of proof that I knew anything of the matter at all Your advice to me to withdraw my connexion with such clubs is quite unnecessary , my standard of medical etiquette is not only as high as any advocated by THE LANCET, but in view of the paragraph mentioned is really higher Fortunately, my reputation among those of my fellow practitioners in this neighbourhood who are most anxious to uphold the dignity of the medical profession is such that I can honestly say they are more annoyed by your paragraph than I am.

If you have any wish at all that I should not be prejudged you will publish this letter in its entirety

I am, Sirs, yours faithfully,

W B. ADDISON.

Parchmore-road, Thornton Heath, Jan. 12th, 1903.

[INCLOSURE.]

" Fernlea," Westbrook road Thornton Heath,
Jan 11th, 1903.

SIR,—It having come to my knowledge that a paragraph appeared in your paper condemning Dr Addison for allowing his name to be issued on handbills distributed in this neighbourhood I wish most emphatically to state that it was done without any consent being obtained from Dr Addison the bills were all distributed before he knew anything about it. I sincerely hope, in justice to Dr Addison and in order to allay anything I may have done to injure his reputation, you will publish this letter I remain, yours truly

F J RUNDLE.

Secretary North Croydon Benefit Slate Club.

⁂ We are glad to learn that Dr W B Addison's name has been taken in vain by the club from which he has severed his connexion.—ED L.

THE MEDICAL MAN, THE CORONER, AND THE PATHOLOGIST

To the Editors of THE LANCET

SIRS,—On Jan. 2nd I was called at 9 30 A.M. to see an infant at 76, Speke-road. On arriving at the house I found that the child had been dead some time, the hands were clenched, the thumbs were turned in, the toes were drawn up, the tongue protruded slightly through the gums, and there was some mucus on the nostrils , the sides of the face were a deep purple. The child had been sleeping in bed with the parents who were in very poor circumstances I sent the usual communication to the coroner s officer and the only acknowledgement I received from the coroner was a verbal message that Dr Freyberger would let me know when he was going to make the post-mortem examination

I inclose a report of the case and you will observe that Mr Troutbeck delivered a little homily to the jury in which he pointed out the importance of employing a pathologist of special skill in these cases. Now I have been making post-mortem examinations in this neighbourhood for 18 years and I have given evidence before all the coroners who have held inquests in south-west London during that time. I have reported scores of similar cases in which the question always arises as to whether the convulsion, if any, which might have caused death arose from partial asphyxia due to overlaying or otherwise, and it stands to reason that the medical man who sees the child lying in the bed and who knows the people and their surroundings is in a far better position to judge of the case than a stranger who does not make a post-mortem examination until three clear days afterwards I may mention here that the child was washed and laid out after I saw it thus removing most of the external diagnostic signs, and there was nothing revealed by the post-mortem examination which could not be seen by any medical man who knew his work. In the circumstances I am utterly at a loss to understand the coroner's remarks, for there was nothing in the case calling for a special pathologist, while there was every reason to call in the medical man who first saw it.

I am, Sirs, yours faithfully,

LEONARD S MCMANUS, M.D., M.Ch R.U I.

St. John s Hill, S W Jan. 12th, 1902.

⁂ We cannot attempt to explain what cases Mr Troutbeck considers " special. Of course, the only medical witness who could help the jury in any practical way in such a case as the one detailed above was the practitioner who first saw the body —ED L.

MEDICAL FOLKLORE—Recently at Luffincott, a little village in Cornwall, an unusual event took place. An agricultural labourer sat in the church porch on Sunday and collected half a-crown in pennies from the congregation, the thirtieth donor giving a half crown and taking up the 29 pence as change. A ring is to be made from the silver coin and by this ring the collector expects to be cured of fits. This is one of the relics of witchcraft which is still to be found in the remote parts of Devon and Cornwall.

THE THERAPEUTICAL SOCIETY—The object of this new society as stated in the rules' which have just been issued, is the advancement of knowledge in pharmacology and therapeutics by the holding of meetings, the reading of papers, the exhibition of drugs and specimens, and such other means as the council may determine." All duly qualified medical practitioners of either sex are eligible for fellowship, and the subscription is 10s. 6*d* a year Ordinary meetings will be held on one Tuesday afternoon in each winter month, from January, 1903, at 4 P M.

[2] Ibid.

BRISTOL AND THE NON-VENTILATION OF SEWERS

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

WHILE, on the one hand, strenuous efforts are being made to discover and to apply really effective methods of ventilating sewers, on the other a reaction has taken place and an impression is gaining ground that this is all a mistake. We are told that it is not necessary to take any trouble whatsoever about ventilating sewers, that such efforts do more harm than good , that ventilators do not remove but create a nuisance , that instead of purifying the sewers we contaminate the air which we draw into them for purposes of ventilation and that then this befouled atmosphere is discharged through grids into the street and under the feet of the pedestrian Better by far close up these grids and let sleeping dogs lie , that is, avoid disturbing the mephitic emanations that may be forming in the sewers below Finally, and to clinch these arguments, the favourable vital statistics of Bristol are given, and we are told that in this town there is no ventilation of any kind for the sewers. All this seems somewhat startling and disturbs the generally accepted principle that sewers should, on the contrary, be very carefully and thoroughly ventilated At first sight, also, the assertion sounds as if some persons believed in what is obviously a physical impossibility It stands to reason that an air tight sewer is an impossibility If the air could not get out of the sewer it would be so compressed by an inrush of storm water that the sewer would explode. Still the statement is repeated over and over again that the sewers of Bristol are not ventilated This is a mischievous assertion, for it provides supine local authorities with an excuse for neglecting altogether a very important part of their duties Complaints may be made that the ventilation of the sewers in some town or part of a town is very unsatisfactory and occasions many inconveniences Thereupon the local authority, instead of attempting to find a remedy, replies that it is thinking of imitating the example of Bristol and of closing all the ventilators, so as to solve the problem by doing away altogether with any sort of ventilation It will easily be seen to what dangerous lengths such a policy of "masterly inactivity' may be carried

In these circumstances it seemed necessary to ascertain on the spot what really had been done at Bristol. The result of these investigations is just what it was natural to anticipate—namely, that there is no brief or simple answer to a very intricate problem that varies in its practical application as the aspects of nature vary It is true that at Bristol there are no grids ventilating the sewers on the street levels , it is even true that there are no ventilating shafts purposely constructed to discharge sewer air at some higher altitude than the road surface but it is not true that there is no ventilation for the sewers Not only is this assertion false, but it is beyond human power to render it true. A sewer must be ventilated more or less or it must burst All that can be said is that it is the "less" rather than the "more" which obtains at Bristol and the only question that can be discussed is whether this is an advantage or not. Then, again, if it is an advantage, would the same principle be equally beneficial if applied to other towns ? These are all questions which are greatly modified by local conditions and what is possible at Bristol may be utterly impracticable elsewhere.

First it must be borne in mind that some of the sewers of Bristol are nearly 100 years old. This the late Mr Frederick Ashmead, engineer of the city, explained in 1877 to the Association of Sanitary Engineers Formerly the ships that came up to Bristol with the high tide were left on the mud as the tide receded The ships built for the Bristol merchants were so constructed as to stand this, but it damaged other vessels The latter consequently avoided the port and Bristol merchants thus secured a sort of monopoly for their ships. From the health point of view the receding tide was an advantage as it helped to carry away what little sewage then reached the river It was not till 1803 that, the Bristol Dock Company having been formed, a new water channel was cut, the rivers Avon and Frome were dammed up, and locks and basins were constructed so that water might be retained when the tide went out and the ships thus be kept afloat. This great work was completed in 1809. But soon complaints began to arise, as bad odours came from the stagnant water of the floating docks or harbour These continued till 1825 and by that time sewers of the length of five and a half miles emptied themselves into the floating harbour, where there was no tide to clear the sewage away To abate this nuisance what is known as Mylne's Culvert was constructed to conduct the sewage directly into the Avon This sewer measures five feet six inches by five feet and has a gradient of 1 in 247 Then another sewer was built which falls into the river above the Tottenham Lock and measures three feet six inches by three feet and has a gradient of 1 in 300 These with older sewers made in all 41 miles of sewers existing at the time of the adoption of the Public Health Act. In 1851 the outlying districts joined to form with the old town the new city and county of Bristol, which had a special committee to deal with health questions It was then decided that the different districts should be drained separately In describing all this Mr Ashmead said, for instance, that the Bedminster district got a sewer four and a quarter by four feet which, going down 40 feet to Nelson terrace, there fell into another sewer six feet by five feet six inches which he describes as "a containing sewer reservoir" with a gradient of only 1 in 300 Then he went on to say that "the sizes of the several sewers in each district are calculated to carry five cubic feet or 31 5 gallons per head per diem for a variable population of from 30 000 to 50,000 per square mile according to the district and a quarter of an inch of rainfall in 24 hours, storm overflows being formed in all cases where possible to provide for a greater rainfall " The several districts have for the most part separate outlets into the tidal river The sewers were not provided with ventilators, but in the high level district of Clifton at low water when the mouth of the sewers was exposed the draught blew up into the houses and an air valve had to be inserted. Thus, in this case instead of there being no ventilation, the ventilation was so extremely violent that it had to be checked The whole of the other sewers—by which presumedly is meant the main collectors—being, Mr Ashmead stated, low level sewers, have double tidal valves fixed at their outlets These valves are self acting, of cast iron, and oval or circular in form They are hung with chains and bedded in indiarubber At low tide they retain the sewage which, gradually filling the up sewer, forces the air back till such time as the accumulated sewage can be let out into the river This constitutes a sort of artificial breathing or pumping, and as it occurs twice in the 24 hours it naturally helps to ventilate the sewers. At the time when this paper was read there were five separate sewer outfalls into the tidal river The cost of building the sewers amounted to £168 071 and the population of Bristol was 202 950 The average death rate before these works were carried out was 28 per 1000 of the population and for the year ending January, 1877, it was 22 7 per 1000 In answer to questions Mr Ashmead professed the greatest ignorance as to the condition of the atmosphere within the sewers. They were all made of bricks—no main sewers were made of pipes—and they were never flushed. 'We never flush them," he declared, ' and have never had occasion to spend a penny for water for flushing purposes in any shape or form, the flow of water is always sufficient." On inquiry I found that this assertion still applied to-day and that no efforts were made to flush the main sewers Nor had anything been done to ascertain the rate at which the air travelled in the sewers In some sewers in the old part of the city what is called sewer gas had been noticed, and in those cases two manholes instead of one were opened so as to set up a thorough draught before allowing anyone to enter

From all this it will be seen that several of the main sewers of Bristol are low level sewers built half a century or more ago and at a time when the necessity of ventilation had not been recognised Then the town began to extend rapidly and outlying districts were annexed to the old historical borough Such extension necessitated the going uphill This is a great fundamental fact Old Bristol lies at the bottom of a basin. There are hills, not on one side, but all round, and these hills rise to a height of 350 feet and are all covered with habitations. Therefore it is not a mixed but a uniform problem. From all points of the compass the topography is the same—namely, the sides of the basin rising up from the flat centre. Consequently one and the same system serves equally well for all districts, this cannot be said of most other towns. In these circumstances it was to be expected that the sewers coming down from the high levels would act as ventilating shafts for the main and large sewers that serve as collectors and are situated on the low levels But this, we are told, is prevented by air valves which open to let the sewage out but close against a pressure of air travelling upwards. Apart from this protection the sewers coming from the high levels are many of them of recent and excellent construction Then they have such precipitous falls that they are not only self cleansing but the sewage travels along them so rapidly that it has not time to decompose and to create a nuisance. Mr. T H. Yabbican, M I C E, the present city engineer of Bristol, reporting on the subject in October, 1898, said —

> *Where sewers are properly constructed with rapid falls* the sewage is not retained sufficiently long for decomposition to set in and no sewer-gas is evolved. I have made experiments to ascertain the rate of flow in the Clifton high level main sewer which has a gradient of 1 in 300 and find that with the dry weather flow the speed is one mile in an hour Most of the branch sewers have much steeper gradients so that any sewage discharged from houses in Clifton or Redland probably finds its way into the tidal river within two hours. When any rainfall occurs the speed of the flow in the sewer is very greatly increased The velocity of a sewer three feet in diameter in a gradient *of 1 in 300 running full is 355 feet per minute.*

Consequently the sewers that run down the many hills on which Bristol stands are not likely to occasion much nuisance, and therefore, *even if not efficiently ventilated, would not cause much inconvenience* But it is a gross error to maintain that the sewers are not ventilated Mr W J Steele assistant engineer of the city, read a paper before the Bristol Association of Engineers on Dec 14th, 1901, and he then said —

> It is not claimed that air cannot enter or emerge *from* the sewers of Bristol because it is practically impossible for any sewerage system to be constructed so that this condition can be obtained nor is it desirable that it should because every *rain storm* would possibly cause the manhole covers to be blown from their *seatings* but it has not yet been proved that any special means for *ventilating the sewers* is necessary

Here, then, we have an admission, an *official* admission, that there is and that there must be some sort of ventilation, but Dr D S Davies, medical *officer of* health of Bristol speaking at the Congress of the Sanitary Institute held at Southampton in 1899 gave *some indication as to* how this ventilation takes place. *He* said —

> *If* any *shafts at all* are required an occasional upcast here and there would suffice to equalise pressure caused by unequal flow admission of *storm* water &c. but even these appear *to* be *superfluous* for should the *sewer-air pressure* increase so as to pass the water seal of the intercepting trap it finds immediate vent up the open soil pipe ventilator and *cannot enter the house* And where the street gullies admit storm water to the sewers, as in *Bristol* a further safety valve through the water seal of these gullies is *afforded with this* advantage, that the escaping air is washed as it bubbles *through and* causes no offence on its escape into the street air The only time indeed, when in *Bristol* we get *smells* or complaints from the sewers is after prolonged drought when the gullies dry and our system approximates to that of a ventilated town this is easily set right by *sending* a water cart round to fill up the gullies.

In regard to the latter point the fact that a gully when dry gives off bad odours would imply either that the gully itself was in a *dirty condition or that* the sewer below was not self cleansing and that the gully was doing more than its share of ventilation but it does not mean that ventilation is an evil or that it would cause nuisance if properly managed The really important point is the admission that the drainage of Bristol is based on a widespread dispersion of safety valves. Many years ago I believe, at Leeds, midden privies were abolished and the houses of one of the best high level districts were *connected* with the sewers The result was an outbreak of typhoid fever in this district Sir William Rawlinson was called in to advise. He found that the street gullies, like those in use at Bristol to-day were all trapped. He *forthwith* ordered the water seals to be broken and thus at once converted the gullies into sewer *ventilators. Thereupon* the typhoid fever epidemic ceased. The position was not unlike that at Bristol. There was a low lying and comparatively unhealthy district with big main sewers that had slight gradients A high level healthy district was invaded by typhoid fever when it was connected by unventilated sewers with the main sewers below As a *matter of fact, it* is incorrect in both cases to say that the sewers were not ventilated—it is only correct to say that no *special means* of ventilation were provided. In both cases the sewers as admitted by Dr Davies in regard to Bristol were ventilated through the syphon water traps. This had a disastrous result at Leeds because in those days the *forcing of* the water seal meant the admission of sewer air into the houses The safety of Bristol to-day is based on the *fact* that when the sewer air has forced its way through the water trap it does not enter into the house. It is the interceptor trap, situated at the foot of the house drain and near the point of its junction with the sewer, that is forced The sewer air then enters the domestic drain, but great care is taken to continue the soil pipe up to, and above, the roof of the house. Of course, it is easier for the sewer air to escape over the roof of the houses than to force its way through a second series *of water traps that are under the sinks or the* pans of the closets But for this modern method of continuing the soil pipe to the roof of the houses the result of not ventilating the sewers into the streets would probably have been as disastrous at *Bristol as it has* been elsewhere. As matters now stand we find a somewhat restricted system of sewer *ventilation* through the house drains, for such ventilation, instead of being constant, only occurs when there is extra pressure in the sewers But by the side of this restricted ventilation there is also some constant ventilation, especially where it is most needed, namely, in the larger sewers, the older sewers and those that have but slight gradients and are therefore not self cleansing These are for the most part on the low level, they approach the water-courses and this is where the storm overflows are situated. Naturally, every *storm* overflow, *though not built for that purpose,* is a sewer ventilator Even if it is provided with a flap valve this must open to let out the overflow, that is to say, it opens just at the moment when the air within the sewer is compressed by the inrush of rain water and there is most need of apertures to act as ventilators and to relieve this pressure Then these old sewers leak in several places, and each leak serves as a ventilator not to mention numerous rat holes Finally—and this applies to all parts of the town—there are a certain number of houses that have *no interceptor* trap whatsoever Their *soil-pipes* plunge directly into the sewers and allow the sewer air to travel up to the roof of the houses without let or hindrance. This is especially the case with all old houses unless the drains have been purposely dug up so as to introduce interceptors, and it is precisely where the older houses exist that the need of sewer ventilation is likely to be the most urgent. Thus at Bristol there prevails a system of ventilating the sewers through the house drains and on to the roof of the houses. Where this is done openly, as for instance at Leicester, many of the householders resist, at Bristol it is done "unconsciously" This, indeed, is the *word* that on several occasions has been used to describe the *method* in vogue at Bristol, and it is claimed that the "unconscious" system of ventilation gives results that are as good as and even better than, those obtained by the deliberate or "conscious" provision of *openings* for the purpose of ventilation.

A statement to which great publicity has been given was made by the medical officer of health comparing Bristol with *Brighton and Croydon.* The average general death rate for the 10 years from 1887 to 1896 was 20 6 per 1000 for the 33 great towns 19 9 for London, 18 9 for *Bristol* including Clifton, 17 7 for Brighton, 14 5 for Croydon, and 13 8, according to local *returns,* for the district of Clifton. The deaths due to fever were 11 per 100 000 for each of the three towns, but the deaths due to diphtheria were 13 for Bristol, 18 for Brighton, and 32 for Croydon, and to diarrhœa 49 for Bristol, 66 for Brighton, and 46 for Croydon This was the annual average during the ten years per 100 000 The fever *mortality,* therefore, was exactly the same whether the sewers were purposely ventilated as at Brighton and Croydon, or only accidentally ventilated as at Bristol, but there was not so high a mortality from diphtheria and diarrhœa at Bristol These figures are given in a report on the non ventilation of Bristol sewers presented to the city council in November, 1898 and *there* it is also stated that the average annual zymotic death rate for 10 years 1881 to 1890 was 2 16 per 1000 at Brighton and 2 12 per 1000 at Bristol, and that that for diphtheria, diarrhœa, and fever combined was 0·98 at Brighton and 0 77 at Bristol Therefore the report concludes that —

> There is no *reason to expect* any improvement in the present satisfactory returns as to the sickness and mortality There is no reasonable hope of improvement but rather the reverse.

This report urges that there is *no risk* of sewer air entering houses as it would be carried to the *roof* of the houses on forcing the interceptor Thus we find here another admission that this probably occurs, and, indeed, there is no attempt to conceal the fact that the interceptor traps are looked upon as safety valves, that is to say, they are not traps to prevent the passage of sewer air, but on the contrary valves to allow the air to escape when there is a pressure strong enough. Thus the ventilation is not prevented, it accidentally occurs in many places and where there is extra pressure it can take place everywhere, for every soil-pipe can then become a sewer ventilator But supposing that other ventilators than the house soil pipes were provided —ventilators that would enable a constant current of air to pass through the sewers, that would prevent the possibility of any pressure capable of forcing the water seal of the house interceptors—what would such an undertaking imply? It has been calculated that some thousand or more such ventilators would be needed and this might cost, it is stated, some £40,000 Why it is urged, spend this large sum to imitate other towns which though they thus ventilate their sewers, obtain inferior rather than better results in regard to their vital statistics It is true that during the last two or three years there has been some increase in the prevalence of typhoid fever and diphtheria in Bristol, still it must be acknowledged that so far as statistics are concerned they supply no evidence to show that the "unconscious" ventilation prevalent at Bristol gives worse results than the "conscious" ventilation applied in other towns The example of Bristol seems to indicate that the ventilation of sewers has been so badly managed in some towns that Bristol without any management at all and trusting simply to the chapter of accidents has obtained results which are quite as good if not better This does not mean that therefore every town authority may as well shut up its ventilating grids and likewise trust to a chapter of accidents Every town has not got a tidal river to occasion the pumping of air in and out of the sewers twice a day Nor is every town built at the bottom and up the sides of a basin as is Bristol Every town has not the same proportion of newly built self-cleansing sewers running down precipitous hills Every town has not got the same proportion of soil pipes prolonged over the roof of the houses ready to act as sewer ventilators as in Bristol, and, above all every town is not constantly swept and purified by the pure sea winds from the Bristol Channel. Therefore it would be very dangerous and unwise to conclude that what obtains at Bristol can be indiscriminately applied elsewhere.

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Exemptions from Vaccination.

THERE are considerable differences in the reasons given by magistrates for exemption or non exemption from vaccination. Recently Mr Makinson, the Salford stipendiary, is reported to have "very unwillingly" granted a vaccination exemption certificate to a young man who thought vaccination detrimental to health and said that a relative was short-sighted as a result of it. The magistrate spoke of the folly and danger of neglecting it but said— ' It would not matter if we could put such cranks in some isolated place but we cannot. However, you appear to have some conscientious objections and you can have the certificate" Here the existence of a general conscientious objection is held to be a sufficient reason for granting exemption. In refusing two applications for exemption certificates at Altrincham in September last Judge Bradbury, who presided on the bench, said that his view of the law was "that an applicant must satisfy two magistrates that his own child was liable to suffer from vaccination and he must bring evidence to that effect. A general objection to vaccination was no good It would be a boon to the country if all magistrates took Judge Bradbury s view In the vaccination returns issued recently it is stated that in 1901 in Lancashire alone there were 5270 exemptions granted and 97,556 vaccination certificates, the births being 126,638 In the meantime small pox spreads apace

The Oyster Scare

Manchester has so far happily escaped any ill effects as regards health from sewage carrying oysters, but the "barrel business' at Christmas is said to have been 25 per cent. less than usual. Many, probably most, of the oysters used in Manchester are American and deep sea oysters, which are, it is believed, safe from sewage pollution which has chiefly prevailed on the south coast. The "Old Shambles" in Manchester are very much given up to oyster bars and shops and the consumption there is said to have been as large as ever and most people have not troubled themselves about the scare. But the crowd may know that the oysters do not come from the south coast Alderman Stanley, "whose firm virtually supplies all Manchester," thinks that the Government ought to insist on the fisheries being registered and that there should be a Minister for Fisheries. Another large firm considers that the scare has injured the "native" and barrel trade nearly 50 per cent, but that it will ultimately benefit trade, "for it was right that more care and discretion should be taken in choosing oyster beds"

Small pox in Salford

At the meeting of the Salford council on Jan. 7th Mr Pinder asked how it was that ten cases of small pox had occurred at the Hope Hospital, which is under the control of the Poor law guardians, "seeing that small pox was a disease against the attack of which every person could make himself secure by vaccination and revaccination." The answer of the chairman of the health committee was that revaccination did not take place in the cases referred to until after exposure to the disease, and he "regretted that people who knew nothing about the disease should set themselves up as authorities on it as against medical men." This, no doubt, is a very proper sentiment, but it implied that blame attached to the guardians, indeed, it was further stated that one of the guardians said it was a shame that "poor old daddies" should be vaccinated and yet the first case was that of a man, 72 years of age. A day or two after, on Jan. 9th, a meeting of the Salford guardians took place and a motion was of course proposed deprecating the tone of the discussion at the council meeting and condemning the action of the chairman of the health committee. This was carried, but about half of the guardians did not vote. Indeed, the lady guardian who proposed the motion, though saying that the board had done all in its power to prevent small pox from entering the hospital or spreading in it, acknowledged that some laxity had occurred. The moral of it all seems to be that the various authorities should work cordially together, that too much vigilance cannot be exercised, and that even ' poor old daddies" aged 70 years and over should have the safeguard of revaccination. However, Salford is to be congratulated on the fact that the chairman of the health committee was able to announce that the death rate in the borough for 1902 was only 19 per 1000 which is a "record" for Salford. Indeed, in regard to small pox it has fared better than many of its Lancashire neighbours, as there have been only about 20 cases.

Joint Hospital for Cheshire

At the meeting of the Northwich rural, Northwich, Winsford, and Middlewich urban joint hospital committee, held on Jan 9th, a communication was read from the Cheshire county council stating that the Local Government Board had sanctioned the borrowing of £2000 for the purchase by the committee of the site for an isolation hospital on the understanding that neither the site nor any building upon it shall be used for small pox.

Baguley Sanatorium.

There are now 28 fever patients in the Baguley Sanatorium belonging to the Withington urban district council. It was opened a few weeks ago Patients are received from the urban districts of Withington, Moss Side, and Levenshulme, and from the districts within the authority of the Bucklow joint hospital board So far the arrangement seems to work well. The patients are brought from their homes in charge of hospital nurses in a large brougham ambulance and when discharged will be taken back in a smaller brougham At Newall Green, about a mile from the sanatorium, corrugated iron buildings have been erected for small pox patients from Withington and Moss Side, which are nearly ready for occupation, should the necessity arise

Jan 13th

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT)

Professor Adolf Lorenz in Liverpool and Birkenhead

Interesting Demonstrations

ON Jan 10th Professor Adolf Lorenz of Vienna visited the Royal Southern Hospital, Liverpool, for the purpose of ionstrating some of his methods of treatment A large ience of medical men filled the clinical theatre. 17 cases congenital dislocation of the hip had been collected by Robert Jones one of the surgeons to the hospital, ether with seven cases of club-foot and some cases of disease with marked deformity Professor Lorenz first nonstrated his bloodless method of reduction in a case of lateral dislocation of the hip in a girl, aged eight years age limit beyond which cases are generally unfavoure. After thoroughly stretching and tearing the tense luctors and extensors and rendering the parts about hip "flail" he reduced the dislocation by causing upper end of the femur to rotate around the lower rgin of the acetabulum and to enter the socket By ced manipulation the socket was made more like an mary acetabulum and he was able to demonstrate arly the slipping in and out of the bone. The thigh was n incased in plaster-of-Paris by Dr Müller in the most shed and perfect manner, the position being that of luction, rotation and extension at a right angle to the ly so as to jam the head of the bone against the anterior t of the acetabulum. Dr Lorenz next proceeded to lace the dislocated heads of the femur in a case of double igenital dislocation in a child, aged three years this being uitable age for his method, the reduction only occupied ew minutes and the patient was fixed in plaster-of-Paris the same manner as in the former case. A demon ation was next given of his modelling *redressement* talipes equino-varus the foot being afterwards placed in ster-of-Paris. The apparatus which he uses for correctg "short leg" in hip disease was next explained. The dience, which consisted of well known surgeons from ndon Birmingham, Liverpool, Wales, &c., was a most thusiastic one, and Professor Lorenz's demonstrations were ceived with great applause, everyone agreeing that in ndity and completeness they could not be surpassed On n. 11th Professor Lorenz paid a visit, among other places ar Birkenhead, to Heswall, for the purpose of viewing the e for the hospital for chronic diseases of children, in hich he took a great interest, and said he hoped that before ng Austria would follow the example of France, Germany, d England by founding similar institutions. He also pressed himself pleased with the arrangements in the cal hospital.

Liverpool Medical Institution.

At the annual meeting of the Liverpool Medical stitution held on Jan. 8th the following list of fice-bearers members of council, and committees was dopted.—President Mr Rushton Parker. Vice-Presidents r J E Gemmell, Dr W Permewan, Mr H Briggs, and r. G W Steeves. Honorary treasurer Mr T H ickerton Honorary general secretary Dr J R. Logan. onorary secretary to ordinary meetings Dr. J Hill bram. Honorary librarian Dr F H. Barendt. Council Ir. E. A. Browne, Dr W Murray Cairns Mr D Douglasrawford, Dr J E. Nevins, Dr W B. Warrington, Mr C. Larkin, Mr W J R. Dunn, Mr F T Paul, r J Pinkerton Dr A. Fisher Mr. C. T Street, nd Dr. A. S. F Grünbaum. Auditors Mr Douglasrawford and Mr G Westby Pathological and Microcopical Committee Professor R. W Boyce, Dr R J M. Buchanan, Mr Douglas-Crawford, Dr R. J Ewart, Dr E. Glynn, Dr Grünbaum, Dr. J Hay Mr R W Monsarrat, Professor C S. Sherrington, and Dr. Warrington ournal Committee Dr Abram. Mr Monsarrat, Dr Barendt, Ir Larkin, Mr G P. Newbolt, Professor A. M. Paterson, Mr W Thelwall Thomas Dr A. J Wallace, and Dr Permewan.

Jan 14th.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary

THE annual meeting of the contributors to the Edinburgh Royal Infirmary was held on Jan. 5th in the city chambers. In the absence of the Lord Provost the chair was taken by Lord Pearson The annual report stated that 9961 in patients had received treatment during the year as against 9552 in the previous year The average daily number of patients was 725 as against 701, the average daily number of children under treatment was 62 as against 61, the average time each patient was under treatment was 26 6 days as against 26 8 days, and the largest number of patients on any one date was 770 against 759 and the lowest number 601 against 591 Of the cases admitted 4878 came from Edinburgh, 553 from Leith, and 3914 from the country The percentage of deaths to cases treated was 8 3 as against 7 8 last year This increase was almost entirely due to the fact that 218 deaths—an unusually large number—had taken place within 48 hours of the patients admission, occurring for the most part in cases of severe injury or in cases of a hopeless nature. The out-patients during the year had numbered 29 765. The ordinary income for the year amounted to £32,621 6s 4d as compared with £33,522 14s 8d. in the previous year, a decrease of £901 8s 4d Voluntary contributions showed a slight net increase as well as the contributions from churches and donations and legacies under £100 The revenue from interest, dividends &c., showed a decrease of £892 6s 8d The receipts from students' fees and income-tax recovered showed increases of £194 14s and £190 7s 1d respectively The ordinary expenditure amounted to £47,193 11s 1d or £2351 3s 2d less than in the previous year The principal increases in expenditure had been in the matter of lights, salaries, and miscellaneous expenses, £106, £321, and £101 respectively The most notable reductions had been £307 in articles of maintenance, £89 in medical expenditure, £1822 in coals £452 in outlay on buildings and £495 in furnishing and repairs. There had been a reduction of £1 2s 8½d. in maintenance and 6s 9½d in medical expenditure for each occupied bed The entire ordinary expenditure during the year including the out-patient department had been £65 1s 10¼d per occupied bed, a decrease of £5 19s 10½d per bed on the previous year During the year legacies and donations of £100 and upwards amounted to £21,007 7s The capital expenditure had again been heavy amounting to £21,248 3s. 1d The leading items of this were £13,618 7s 4d from the extension fund for the new pavilions, £2558 19s 6d from the general fund for drainage reconstruction works, and £3602 11s 4d for the overhauling and renewing of the heating system The total free income for the general fund fell short of the total expenditure under that account by £10 451 10s 5d and the managers had to meet that deficiency by drawing on the accumulated surplus from the revenue of former years. The average number of nurses and probationers during the year was 199, being the same as in the preceding year The number of applications for admission to the nursing staff was 656 as against 627 in the previous year Blair House continued to prove of increasing value as a health resort and home of rest for the nurses It was expected that the new ear and throat pavilion and the ophthalmological pavilion would be ready for furnishing in January and March respectively The total number of patients admitted to the Corstorphine convalescent home had been 1237, a decrease of 21 on the numbers for the previous year The daily average in the convalescent home had been 63 2 as compared with 64 4 last year Of the total number 865 had enjoyed a full three weeks' residence in the home. The managers regretted to state that the total income of the convalescent home had again failed to meet the outlays, the deficit this year being £1047 8s 8d They strongly press the claims of the convalescent home as worthy of a much larger share of support from the public. The managers recorded their grateful appreciation of the unwearied services of the medical and surgical staff and of the scientific skill and professional ability displayed by them. In conclusion, while gratefully acknowledging the response made by the people of Scotland to the claims of the infirmary on their liberality, the managers emphasised the fact that the ordinary expenditure was far in excess of the ordinary income and that this condition became each year more serious. If it were not for occasional contributions and legacies of considerable magnitude the infirmary might be placed in a state of financial embarrassment. They earnestly appealed for increased financial support so that the ordinary income might be sufficient to meet the ordinary expenditure The chairman, in moving the adoption of the report, drew attention especially to the reduction in the ordinary expenditure and emphasised the fact that though the closest attention was paid to economy the greatest care was taken that nothing should be done which would in any way interfere with the efficiency of the work. The motion for the adoption of the report was then unanimously agreed to and it was remitted to a committee of contributors to consider and to report upon to a future meeting

Resignation of Sir W Muir, Principal of the University of Edinburgh

At a meeting of the Senatus Academicus of the University of Edinburgh which was held on Jan. 10th the following minute was adopted —

The Senatus having been apprised of Sir William Muir's resignation of the principalship of the University and of its acceptance by the university court resolved to give permanent expression to their deep sense of respect and affection for one who has so long presided over them and to the great regret with which they bid him farewell The Senatus were proud to receive Sir William Muir 18 years ago after he had passed through a distinguished administrative career in India and had attained a high reputation as an Oriental scholar and historian and they now desire to record that during his tenure of office by his unfailing kindness and nobility of heart he has greatly endeared himself to all connected with the university and that by his courtesy in intercourse and by the exercise of a generous hospitality he has maintained and promoted relations of amity and friendship between the University and all sections of society The Senatus recall with appreciation Sir William Muir s exemplary and assiduous discharge of the many duties of his position his warm interest in all that concerned the welfare of the University and the open handed munificence which characterised his tenure of the principalship It is the earnest desire of the members of the Senatus that he may be long spared to his many friends and that the remaining years of his life may be rich with blessings

The Principalship of the University of Edinburgh

The question of who is to succeed Sir William Muir as Principal of the University of Edinburgh is causing some interest and some talk. Various names have been mentioned, but the one which receives most attention is that of Sir William Turner, the present professor of anatomy in the University Sir William Turner has been for many years a strong University personality, his scientific position is acknowledged and his election to the chairmanship of the General Medical Council may be taken as the proof of the opinion formed of him by his colleagues on an important board It is natural, therefore, that university and medical interest should look to him as a possible and a suitable candidate. It is, however, understood that there are technical difficulties in the way It seems that a university professor is not at liberty to retire from his chair when he likes and at the same time to claim his retiring allowance, and it is not suggested that Sir William Turner should forego the pension to which he may be entitled, to take on the duties of principal on a scale of remuneration below what his professional pension might be This somewhat difficult point has, it is understood, to be settled by the University court, and it is expected that matters may be practically settled before the end of the current month

Jan 13th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Royal Victoria Hospital, Belfast

AT a meeting of the construction committee held on Jan 8th it was announced that all the subscriptions promised, with the exception of about £3000, had been paid and that the remainder (less about £500 which owing to deaths &c., would be uncollectable) was expected to be available before the building was opened It is hoped that the hospital will be opened by the King

Rainfall in Ulster in 1902

The total rainfall in Ulster for 1902 was 40 07 inches, which is below the average (41 12) for the previous 27 years 1902 was an erratic year, the rainfall in the first six months being under the average, only 16 85 inches, in the other part of the year 23 22 inches were recorded In the wettest part of the year—July, August, and September—13 85 inches fell.

Ulster Medical Society

A meeting of this society was held on Jan 8th, the President, Dr John Campbell being in the chair Professor J A. Lindsay opened a discussion upon Difficulties of the Medical Examiner in Life Assurance Work. He condemned the excessively elaborate inquiry forms adopted by some assurance companies as tending to diminish the sense of responsibility on the part of the medical examiner and by harassing him with a multitude of irrelevant details his attention was apt to be diverted from those outstanding facts upon which the eligibility of an applicant for a life assurance policy really depended. It was vexatious to be expected to inquire into the cause of death of grandparents, to record the colour of the applicant's hair and eyes, or to put such pointless questions as "What is the applicant's temperament?" "Is there any danger of lack of acclimation?" In the long run the companies must trust their medical examiner, but they might fairly require him to write down that he had inquired into the leading facts in the family and personal history, examined the principal organs of the body and tested the urine. The examination of an applicant should be thorough and systematic but not harassing or over elaborate, and an attitude of suspicion should be avoided. It should be remembered that an applicant was not a patient and that examination for life assurance was a different matter from making a diagnosis in a difficult case. The interpretation of the applicant's history was often a difficult matter Wrong statements were often made by applicants, not usually, perhaps, from any conscious attempt to deceive but rather from the unconscious play of self interest. Deaths from phthisis were often concealed under such expressions as "died from the effects of a chill," or "as the result of a wetting," or "from hæmorrhage from the throat." Deaths from cancer and from delirium tremens were often veiled under various periphrases Long life or short life as a family trait was a fact of the first importance Of all the factors relating to longevity none was so important as the applicant's inherited tendency As Heine had remarked, "We can't be too careful in the choice of our parents." Several deaths in one family possessed a very different significance at different ages. In childhood one of the infective diseases was usually the cause, in adolescence tuberculosis, and at middle life premature vascular degeneration These facts had a very different degree of value as bearing upon life prospects. A family history of phthisis was not so seriously viewed now as formerly but its importance was not to be denied. Members of consumptive stocks, however, who had passed the dangerous age (from 15 to 3 years), who had well developed chests, and who were i vigorous health might be safely accepted with a moderate "load," which might be remitted after the age of 4 years, if all was satisfactory A history of pleurisy wa important as many pleurisies were tuberculous in origin, but an acute pleurisy, fully recovered from and leaving neither local signs nor constitutional impairment, did not call for any addition. A history of an attack of hæmoptysis without signs or symptoms warranted a moderate "load" which might be remitted after the age of 45 years A history of syphilis called for a careful scrutiny of all the organs, especially the arteries and the nervous system If the applicant had received adequate treatment and had been free from all symptoms for four or five years a small addition would meet the case. The possibility of some of the late effects of syphilis (e g , loqomotor ataxia) should be borne in mind. The applicant's occupation was very important. The speaker dealt at length with the mortality and life prospects of the various trades and professions. Obesity and underweight should receive careful attention. Obese persons bore acute diseases badly, they were sometimes, though by no means always, free livers, and were prone to gout. Spare persons were often good lives but tuberculosis, diabetes, and other causes of wasting should be borne in mind. An unduly frequent pulse if not due to obvious nervousness, should cause watchfulness It might be the only sign of concealed alcoholism. Tremor of the tongue might have a similar significance Many applicants were untrustworthy on the subject of alcohol In a doubtful case they might get valuable hint from (1) undue frequency of the pulse, (2 tremor of the tongue, and (3) dyspepsia, especially morning sickness The relation of piles hernia varicose veins, atheromatous arteries, emphysema, diabetes, asthma, albuminuria and heart disease to life assurance was fully dealt with. small quantity of sugar in the urine of an applicant over years of age without thirst, wasting or other proof o diabetes, should lead to the postponement, not the rejection of the case. Many of these patients got well. Albuminuria was as a general rule, a bar to acceptance The cases o so called "cyclical" or "functional" albuminuria were very difficult. Such cases could not be safely taken a ordinary rates but much depended on the applicant's age. He was inclined to be suspicious of these cases and to hold that a substantial proportion of them ultimately developed organic renal disease. The question of heart disease i its relation to life assurance raised many interesting questions Aortic cases and cases of mitral stenosis were probably uninsurable. Mitral regurgitation was the difficult point Many of these cases went on indefinitely If mitral regurgitation could be shown to have existed for four o five years without giving rise to symptoms or producing ecognisable hypertrophy or dilatation, if the arteries were ound and the pulse was normal, if the applicant's general ealth was good, his habits were regular and his occupa ion was suitable, the assurance companies would do well to onsider the propriety of admitting such cases to the advan ages of a limited or 'tontine' policy. In the discussion which followed Dr. Calwell, Dr. W. B. McQuitty, Dr. Nelson, and Sir William Whitla took part.

Irish Education.

The Royal Commission on University Education has con- luded its work and the report it is said will be ready next onth. On Jan. 12th Lord Londonderry (Minister of Educa- on) and Mr. G. Wyndham (Chief Secretary for Ireland) ad a private conference in Belfast with members of the oint committee of the Chamber of Commerce and the echnical committee of the Belfast Corporation and repre- entatives from Queen's College in reference to the scheme or the establishment of a system of commercial education in onnexion with Queen's College. It is hoped that this will be arried through and that the Government will make a special nancial grant.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A Medical Information Bureau.

IN my letter which appeared in THE LANCET of Jan. 10th . 137) I mentioned the new bureau of medical information hich has recently been started in Paris. The bureau is under e municipal council of Paris and will prove of great value foreign or provincial medical practitioners who come to ursue their medical studies in Paris. The former are often uite at sea on arriving in Paris, especially if they do not now French. Even if they have a letter of introduction to ome eminent Parisian practitioner—who for the very reason hat he is eminent is correspondingly busy and cannot act s a cicerone—they have infinite trouble in getting the nformation which they require as to what course of ectures to attend, what medical men eminent in par- icular lines to see, what hospitals to go to and he days and hours at which certain lectures and lemonstrations take place, so that they waste their time nnecessarily. Besides the purely professional establish- ents, such as hospitals there are plenty of organisations nteresting to medical men about which even Parisians them- elves know little or nothing, such as infirmaries con- alescent homes, the water-supply department, the sewage lepartment, crematoriums, prison infirmaries, the municipal aboratory for identifying adulterations, the Morgue, and various matters connected with forensic medicine. Dr. Blondel, the secretary general of the International Medical Press Association, who made an expedition throughout Europe for the purpose of study in 1900, was greatly struck with the accounts which he received from foreign medical men of the difficulties which they encountered when they went to Paris. The idea of the information bureau came into his head and he accordingly urged M. Brouardel, who was then Dean of the Faculty of Medicine, to set aside a small room and one attendant in the buildings of the Faculty so as to make a beginning with this bureau. This seemed a simple plan, only unfortunately the Faculty had no attendant whom they could spare and no funds wherewith to pay a new man for the post. Dr. Blondel then approached the municipal council with a view to a grant. M. Brouardel, however, preferred that the money should be procured from the Government and he obtained from M. Liard a promise of a grant of 1000 francs to which sum the Faculty promised to add 500 francs. Neither the 1000 francs nor the 500 francs were ever paid in, and so, after waiting for six months, Dr. Blondel again approached M. Brouardel. He, however, said that as he was just on the point of resigning he did not wish to undertake any new scheme but would leave the matter to his successor to initiate. Six months more went by, but when the new dean, M. Debove, was nominated Dr. Blondel laid the matter before him and met with a gratifying response. M. Debove then, not considering that he had the power to decide the question himself, called together the council of professors. M. Pozzy, to whom the question was submitted for considera- tion, reported in its favour, the council approved, and the dean was charged with the duty of preparing a detailed scheme. The dean in his turn introduced some modifica- tions into the original scheme of Dr. Blondel which had been approved by M. Pozzy and the Faculty in that he wished instead of having a special employé acquainted with foreign languages and sitting in a special room to make use of one of the attendants of the Faculty who was but little of a linguist. As for the necessary expenses they must con- tinue to rely on the generosity of the municipal council. Finally, Dr. Blondel appealed to two municipal councillors, M. Dausset and M. Felix Roussel, who laid his petition before their council. The petition was granted and at the meeting of the council held on Dec. 31st a grant was made of 3000 francs for the creation of a bureau of medical information on condition that it should be installed in rooms in the Hôtel de Ville, the Assistance Publique, the Sorbonne, or the Faculty of Medicine according to which appeared the most convenient situation. It is hoped that the bureau will be in working order within the next two or three months. The employés will all be able to speak other languages than their own and will be well versed in the information which they will have to give. They will also have on hand reference cards contain- ing information kept regularly up-to-date (*fiches tenues régulièrement à jour*).[1] A list of foreign medical men residing in Paris, of whom there are some 500, will also be kept, classified according to nationalities, and among them there will be established a community of *camaraderie* so that their compatriots will always be sure of a welcome and will be able to get the most complete information.

Obituary.

Dr. Panas, formerly President of the Academy of Medicine, died on Jan. 5th. He was 71 years of age but his intellectual faculties were in no way abated. He was a Greek and was born at Cephalonia in the Ionian Islands on Jan. 30th, 1831, but when quite young he came to France to study medi- cine in Paris. In 1854 he was elected an *interne*, later he became assistant demonstrator in anatomy and finally prosector. The remarkable success which attended him in the various competitive examinations drew the attention of Nélaton who took him under his wing. In 1863 Panas was nominated *agrégé* of the Faculty and soon afterwards he was elected surgeon to the hospitals. He served as surgeon to the following hospitals in succession: the Bicêtre, Lourcine, Saint Antoine, and Saint Louis. During this period of his career he was naturalised. He had already written much upon general surgery and had contributed to Dechambre's Dictionary articles on the pathology of diseases of the joints, which still remain as authoritative utterances. He then devoted his attention to ophthalmology, in which department of science he had a long and brilliant career and his "Anatomy of the Nasal Fossæ and the Lacrymal Canals," his book on "Strabismus and Ocular Paralysis," his treatises on the "Pathological Anatomy of the Eye" and on "Inflammatory Affections of the Internal Tissues of the Eye" still rank as classics. In 1879 he was appointed to the chair of clinical ophthalmology at the Faculty of Medicine, a post which had been specially created for him. This post he resigned last year being worn out by the painful and lingering malady to which he at length succumbed. He was a member of the Society of Surgery and held the presidential chair in 1877. He was also Officer of the Legion of Honour.

(FROM OUR OWN CORRESPONDENT.)

Supposed Discovery of the Germ of Rabies.

THE resemblance of hydrophobia in its clinical and anatomical characters to other infectious diseases the specific germs of which are now known is so complete that little doubt of its microbic origin has been entertained not- withstanding the failure of the many efforts which have been made to isolate the germ. Its transmissibility by inocula- tion, the presence of a period of incubation after the inocula- tion, the possibility of stamping out the disease by certain precautions, and its resemblance in many details to tetanus, have all pointed strongly to such an origin. But although many organisms have been described from time to time as holding a causal relationship with rabies no single one of them has stood the test of a rigid proof Memmo, for example, described a blastomyces in this connexion, while Bruschettini demonstrated an organism holding an intermediate position between a saccharomyces and an oidium. Others, as Pasteur, Chamberland, and Roux, ascribed the same rôle to micrococci of different sizes with cultural and staining peculiarities of various kinds A remarkable fact in regard to many of these organisms was that they appeared when inoculated into animals to produce symptoms very similar to, if not identical with, those of rabies. It has now been claimed by Dr Sormani, professor of hygiene in the University of Pavia, who has devoted many years of study to the subject, that he has succeeded in isolating a microbe which responds to all the tests and which he is confident is the true causal organism of the disease. The previous failures to identify this germ as the specific one Professor Sormani ascribes to its polymorphism, and he believes that certain of its forms and stages have been seen and described by other observers who, however, missed the connecting links and so failed to establish the unity which he asserts exists between them These phases depend upon the mode of development and the cultural medium, according to which the microbe takes the forms sometimes of micrococci, sometimes of bacilli, or very rarely of blastomycetes, its colonies on the medium having a cloudy or fleecy, or at times a branching aspect. The microbe though often to be found in microscopic preparations of the tissues, is best studied in pure cultures Being one of the smallest of known organisms it can be seen only with the higher powers of the microscope (1200 diameters) and for its minute detailed study requires the highest magnification obtainable If Professor Sormani s observations and inferences be confirmed his discovery will doubtless lead to the modification and simplification of the present complicated technique for inoculation against rabies. It may also point the way to the recognition of the specific cause of other diseases the causal organisms of which may have escaped observation hitherto only on account of their minute size or their polymorphism. After the many disappointments of the past, however, it is necessary to be cautious in accepting the discovery as an established fact until confirmatory observations can be made.

---

[1] "Fiches" is an untranslatable word. It means among other things something analogous to the "card catalogues" which are to be found in public libraries.—ED. L.

The Death rate of Italy

Statistical records of the mortality amongst the whole population of Italy have been available since 1885 They are always carefully and clearly arranged, but it is unfortunate that they are published so late that at the beginning of the year 1903 we know nothing officially of the returns of 1902 or even of those of 1901. Indeed, it is not more than two months ago since the death statistics of 1900 were published In that year the mean general rate of mortality was 23 8 per 1000 of population, an excessive amount when compared with that of other countries (excepting Russia, Austria Hungary, and Spain), and also excessive when contrasted with that of the previous triennium 1897–99 in Italy itself, which was only from 21 to 22 per 1000 This latter figure denoted a reduction of the death roll of the triennium 1885–87 (when the rate was from 26 to 28 per 1000) of some 200,000 persons per annum and that thus not less than 4 000,000 persons have been saved by improved hygiene from disease and its concomitant and consequent economic loss Professor Celli, in commenting upon these statistics adds that he understands from official sources that the rate of mortality for 1901 shows a diminution on that of 1900 being only 21 95 per 1000 He points out that even this figure leaves an immense amount to be desired before the hygienic ideal can be said to have been reached since in Norway and Sweden, which countries have the lowest mortality, the rate has been reduced to about 15 per 1000 Comparing the death rates in different parts of Italy with one another it is found that all the provinces with a death rate above the mean belong to Southern Italy and the islands, whilst the provinces with a mortality below the mean belong to Northern and Central Italy Of the former Foggia and Potenza come out worst with a rate of 30 4 and 30 per 1000 respectively, while of the latter Pisa and Treviso come out best with a rate of 19 5 and 19 2 respectively Of the principal towns the worst are Catanzaro and Siena with a rate of 41 and 39 respectively, whilst Sondrio and Porto Maurizio stand best with rates of 18 8 and 19 5 respectively But in general it is found that as regards the towns the majority of those with a less mortality belong to Central or Southern Italy, whilst those with a larger mortality belong to the northern provinces. Of the larger cities Naples has a mortality of 25 8, Venice 24 9, Bologna 24 3, Genoa 23 8, Milan 22 4, Turin 22 3, and Rome 21 7 per 1000. The preeminence of Rome for salubrity amongst the larger Italian cities is now generally recognised in Italy itself, but deserves to be more widely known abroad where the impression still prevails that it is unhealthy It is unfortunately still very common for patients and even ordinary visitors to Italy to be cautioned by medical men in England and America against Rome on account of its supposed unhealthiness and the danger, which is quite imaginary, of falling a victim to malarial fever there. The above statistics are a sufficient answer to the charge of general unhealthiness and as regards malarial fever the disease is practically unknown in the city and is never contracted there by the foreign visitor

NEW YORK.

(FROM OUR OWN CORRESPONDENT)

Tent Life for the Tuberculous Insane.

IT has long been recognised that pulmonary tuberculosis spreads with great rapidity among the insane. This is not due to any special predisposition on the part of those who are mentally unbalanced to contract the disease but is owing to their dirty personal habits. Therefore, in every asylum for the insane there should be ample and efficient means of isolation. Dr A. E Macdonald, superintendent of the Manhattan State Hospital, Ward's Island, New York City, inaugurated in 1901 a system of "tent care" for the tuberculous insane which is said to have been attended with excellent results. The tents used were large and airy with boarded floors and fitted with every convenience. They were pitched on elevated ground and surrounded by abundant shade. Each tent contained 20 beds. During the year 81 patients were thus treated, and in that time 19 deaths occurred among them, a percentage of 23 45 out of the total number of cases treated. When, however, all the deaths which occurred in the hospital during the same period are taken into account these figures make the percentage of those succumbing to tuberculosis as low as 8 8. Ten ye ago the death rate from pulmonary tuberculosis at the M hattan State Hospital was 17 8 per cent. of the total deat and one year ago 9 8 per cent. of the total deaths resul from this disease , but under the "tent care" of these ca the percentage of 8 8 has been established, the lowest in t history of the institution Dr Macdonald is so satisf with the success of the system that he has provided for extension of it

Overcrowding of Street and Elevated Railway Cars in New York.

Dissatisfaction with the manner in which the street c and elevated railway service of New York is managed b prevailed for a long time. At certain hours of the day wh persons are going to and from their business the cars a crowded to an almost incredible extent. Men, women, a children are jammed together like sardines in a box, a it is a common sight to witness a car so full that would be an impossibility to get another person in. T matter has been discussed for years and many remedi have been suggested to relieve the congestion Nothin however, has been done and at the present time the sit tion is more intolerable than ever Recently some of t leading women of the city have taken the matter up a have entered a vigorous protest against a continuance the existing state of affairs. The Merchants' Association New York has followed suit and through its Committee Franchises and Transportation has issued a manifesto which an urgent appeal is made to ministers of all denomin tions and to all members of the medical profession to u their influence to save women from the unhealthy a demoralising effects of travelling on crowded cars T manifesto in question declares that public decency is o raged, public morality assailed, and public health endanger by the promiscuous personal contact with others forced up all members of this community who use street and elevat railway cars The document ends with an appeal to the 60 physicians of the city to further the movement against t present abuse of the system by making clear to their patien the physical harm that comes from this abuse The major of the lay papers of New York have entered into the fr with zest and are attacking the corporations which contr the street railway system with energy The *Medical Record* and other New York medical journals have commented on the subject editorially and have pointed out that the excessive overcrowding permitted on all the street railways is highly prejudicial to health in every way

Dr Lorenz in New York.

Professor Lorenz of Vienna, who came to this country some weeks ago to operate upon a child of Philip Armour of Chicago for congenital dislocation of the hip has made something of a triumphal progress through whatever part of the United States he has travelled. In New York he was received by the medical profession generally with the same amount of enthusiasm as elsewhere and he demonstrated his skill at different hospitals of the city before a large audience of its foremost surgeons. At a meeting of the section of orthopædic surgery of the New York Academy of Medicine held on Dec. 19th the whole time was taken up by an address by Dr Lorenz and by a discussion of his methods. The address was brief, merely giving a description of some of the principles of orthopædic surgery upon which Dr Lorenz has founded his bloodless operation for reducing congenital dislocations of the hip and for dealing with club-foot and wry neck He also claimed that this method is to be preferred to the open method, and whenever possible far in advance of mechanical measures. In the discussion which followed, and in which the leading orthopædic surgeons of New York took part, there was displayed a remarkable unanimity of opinion as to the extraordinary skill of Dr Lorenz as an operator and the belief was expressed that, given the necessary manipulative dexterity, his principles were correct

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

Plague in Queensland

THE bubonic plague has broken out again in Queensland, the first case being in a Chinaman at Bundaberg The State has been declared infected so far as quarantine and plague regulations are concerned.

Ptomaine Poisoning

Two instances of serious ptomaine poisoning have occurred recently one in Victoria and the other in New South Wales In the first case over 100 people at a picnic were attacked with thirst, abdominal cramps and pains nausea, and extreme prostration. All the affected persons had partaken of sandwiches of minced ham. In the second instance nearly a dozen people at Randevick were attacked in somewhat similar fashion after eating some cooked meat purchased at a ham and-beef shop In the Legislative Assembly of New South Wales the Premier was asked if he would cause inquiries to be made into these cases for the protection of the public The Premier replied that the subject was being investigated and would be considered by the Board of Health with a view to take such action as might seem necessary in the general public interest.

Concentrated Milk

A milk company was recently convicted for selling what is known as concentrated milk. An analysis showed that it contained boric acid and formalin in the proportion of 1 part in 10 000 Expert evidence was given that concentrated milk would not keep without the addition of preservatives The magistrate said that if customers asked for condensed milk they expected to get it pure and not mixed with preservatives He inflicted a fine of £2, with costs. The milk company does a large business both in Sydney and in Melbourne

Adulterated "Raspberry Vinegar'

At the last meeting of the Board of Public Health of Victoria a report was submitted by the Government analyst on his examination of 44 samples of so-called 'pure raspberry vinegar" Only one was found to be free from poisonous adulteration. The principal ingredients were coal tar dyes chemical preservatives salicylic acid, saccharin, dulcin, and cochineal. The Board simply said that it was desirable that the Government should take steps to lessen the use of such adulteration.'

Hospital Affairs

The finances of the various Melbourne hospitals have been seriously disturbed by the reduction of the Government grant and a meeting of representatives of the institutions concerned was held recently to consider the position It was pointed out that the reduction came with great harshness at the present time, when the institutions could not pay their way even with the unreduced grant. It was resolved—

> That a deputation be appointed to wait upon the Treasurer to point out to the Government the difficulty of retrenching to the extent proposed and to discuss the best method of obtaining a revenue from amusements and other sources for the purposes of the charities

—At the Melbourne Hospital the deficiency in the finances is estimated at £6000 for the year and the committee says that it is impossible to reduce expenditure The question of imposing a special charity tax is being seriously considered as the only way out of the difficulty At the last meeting of the committee of the Melbourne Hospital a letter was read from the Faculty of Medicine offering to advise the committee prior to any appointment by the committee of new members of the honorary medical staff. It was resolved to reply, thanking the faculty for the offer and stating that should any occasion for a conference arise the faculty would be advised of it.—The board of management of the Hospital for Sick Children, Sydney, has leased from the committee of the Carrington Convalescent Home a cottage for the reception of children to be under the sole control of the authorities of the Children s Hospital. Two wards, each containing seven cots, will be fitted up one for girls and the other for boys This will relieve the hospital of many chronic cases where the patients are yet not well enough to be taken into the regular convalescent homes The new buildings for the out-patient department of the Children's Hospital in Valentine-street will soon be completed.

Obituary

Dr Alexander K Morson, a well known practitioner of North Sydney, died at his residence, Kirrivilli Point, on Nov 15th He received his medical education at Edinburgh, where he took the diploma of Licentiate of the Royal Colleges of Physicians and Surgeons in 1863 and graduated as M.D the following year He practised for many years at West Maitland, but had latterly retired from active work, though he was greatly interested in benevolent institutions and was for a long time a member of the committee and trustee of the North Shore Hospital

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—At a recent meeting of the Liverpool School of Tropical Medicine, at which Sir Alfred Jones K.C M G, the chairman, presided Major Ronald Ross C B. F R.S. was heartily congratulated on the high distinction that he had attained by winning the Nobel Prize. It was announced that since the last meeting of the committee the sum of £10 600 had been collected or promised towards the foundation of a chair of Tropical Medicine in University College, Liverpool which had been offered to the University authorities and accepted, also that Major Ross had been unanimously elected to the Professorship, and that in future his title in connexion with the school would be The Sir Alfred Jones Professor of Tropical Medicine ' The Walter Myers Lectureship in Tropical Medicine having become vacant Dr J W W Stephens who recently joined the staff of the school, was unanimously elected to fill that position. Dr Stephens was until recently a member of the

Commission of the Royal Society on Malaria and has been closely identified with research in tropical medicine A letter was read which had been received by the chairman from Lord Lansdowne offering his congratulations to Major Ross, to the Liverpool School of Tropical Medicine, and to all those who contributed to the establishment of the institution

Medical Magistrate —Mr John Lynn Thomas, C B., F R.C S Eng , L.R.C P Lond , has been appointed on the commission of the peace for Cardiganshire, his native county

Bristol Dispensary —The annual meeting of the subscribers of the Bristol Dispensary was held on Jan. 9th The medical report stated that 11,264 fresh cases had been treated during 1902, exclusive of 483 midwifery cases The financial statement was satisfactory and showed a considerable increase in subscriptions

Cardiff Infirmary —The annual meeting of the ladies' committee of the women's ward in the Cardiff Infirmary was held on Jan. 3rd. The statement of accounts for 1902 showed that a favourable balance of £411 remained. The number of beds maintained by the committee is now 15 The women's ward contains 16 beds and it is hoped that before long the whole of the beds will be supported by the ladies' committee.

Infringement of Burial Regulations —At the Bristol police court on Jan 9th a firm of undertakers were summoned for interring a stillborn child without informing the chaplain of the cemetery that there were two bodies in the coffin Evidence showed that a woman had died in childbirth and that the mother and child were placed in the same coffin. The magistrates imposed a penalty of £2 with £2 2*s* costs

Donations and Bequests —Under the will of Mr Abraham Samuel of Louth £5000 are bequeathed to the Louth Hospital and £200 to the Lincoln County Hospital. The Jews' hospital at West Norwood benefits by a sum of £100 —Messrs. G W and Charles Crompton have subscribed £1000 for the endowment of a bed in the Derbyshire Royal Infirmary in memory of their late brother, Mr E. A. Crompton, of Windley Hall, Derby

The League of Mercy —The honorary secretaries of the League of Mercy have received from the Prince of Wales Grand President of the League, and also President of King Edward's Hospital Fund, a letter conveying to the officials and members of the League his thanks for the sum of £8000 handed over by them to King Edward's Hospital Fund This substantial contribution is an increase of £1000 on the amount received last year

The London Association for the Prevention of Premature Burial has now appointed a medical secretary—viz., Dr J Stenson Hooker—having come to the conclusion that this step would add more weight when the various matters dealt with by the association are brought before the medical profession and Parliament. The offices of the association are at 44 Gloucester place, Portman square, W Annual subscribers of £1 1*s* are entitled to copies of all pamphlets and to death verification The minimum subscription is 5*s* per annum.

Folkestone Medical Society —The annual meeting of this society was held on Jan. 9th at the house of the President, Dr T Eastes 20 members were present, Dr W J Tyson being in the chair in the unavoidable absence of the President. The following officers were elected for 1903 —President (re-elected) Dr Eastes. Vice-Presidents Dr Hackney and Dr Tyson. Committee of Management Mr Gilbert, Mr Gore Mr Read, Mr Murdoch and Dr Sworder Library Committee Mr Madden, Mr Livington, and Dr A Gordon Wilson Honorary secretary and treasurer Dr Calverley

"Freeing Animals from Parasites"—An American inventor has patented a method of freeing animals from parasites. The process consists in completely immersing the animal in a bath and passing an alternating electric current of substantially low voltage through the animal and the parasite while so immersed The nature of the fluid in the bath is not stated The illustration shows a cow totally submerged in a tank of fluid. Electrodes are attached to the cow but there does not seem to be any provision for respiration or any means for bringing the animal's head to the surface of the fluid Full particulars are given in the *Official Gazette* of the United States Patent Office, published on Dec 23rd, 1902.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index)

Ayr District Asylum, Ayr —Two Assistant Medical Officers, unmarried Salary £150 and £120 with board lodging laundry and attendance.
Birkenhead Borough Hospital.—Senior Resident Male House Surgeon Salary £100 per annum with board.
Birmingham General Dispensary —Resident Surgeon, unmarried. Salary £150 per annum

x Infirmary and Dispensary —Senior and Junior House rgeons.—Salary for the senior £130 and for the junior £100 per num, with apartments board and attendance.

h Lying-in Hospital.—Physician to the Out patients

ester Infirmary —House Surgeon. Salary £100 per annum th board residence and washing

rshire Royal Infirmary —Two House Surgeons. Also House iysician. Salary in each instance £100 per annum, with apart ents board &c. Also Assistant House Surgeon for six months. alary at rate of £60 per annum, with apartments board, &c.

rton Asylum Salisbury —Assistant Medical Officer unmarried alary £150 per annum, with board lodging and washing

r Yarmouth Hospital.—House Surgeon. Salary £90 per nnum, with board, lodging and washing

venor Hospital for Women and Children Vincent square, estminster —Assistant Surgeon

stead Hospital.—Resident Medical Officer for six months. alary at rate of £120 per annum with rooms coal and gas

orn Union —Medical Officer Salary £100 per annum.

tal for Sick Children Great Ormond street, London, W C —ouse Surgeon unmarried, for six months. Salary £20 with ard and residence.

er Institute of Preventive Medicine.—Studentship of the alue of £150 for the purpose of Research in the Department of athological Chemistry

s College Hospital. London —Senior Medical Registrar and utor Also Clinical Pathologist. Salary £250 a year

hester Royal Infirmary —Resident Medical Officer un narried. Salary £150 per annum, with board and residence.

nt Vernon Hospital for Consumption Hampstead.—Four linical Assistants.

Hospital for Women —Pathologist (female) Also Anæs hetist.

h Riding Asylum Clifton. York —Senior Assistant Medical fficer unmarried. Salary £150 rising to £200 with apartments, oard washing and attendance

ton Lancashire, County Asylum Whittingham.—Assistant ledical Officer unmarried. Initial salary £150, with apartments oard, washing and attendance.

ar Hospital for Accidents Poplar E.—Assistant House urgeon for six months. Salary at rate of £50 per annum, with oard and residence

hill, Surrey Earlswood Asylum.—Two Assistant Medical fficers unmarried Salary of the senior £160 rising to £200 of he junior £130 rising to £150 with apartments board, and wash ng in each case.

hester, Saint Bartholomew's Hospital.—Assistant House urgeon. Salary £100 per annum, with board, lodging washing iring and light

al College of Surgeons of England.—Examiner in Dental urgery

al General Dispensary 25 and 26, Bartholomew-close E.C —Physician.

al Hants County Hospital, Winchester —House Physician, un narried Salary £65 per annum, rising to £75 with board esidence, &c.

al Isle of Wight County Hospital, Ryde.—Resident House Surgeon. Salary £90

al London Ophthalmic Hospital (Moorfields Eye Hospital) City road E C —Junior House Surgeon also Third House Surgeon. Salary £75 and £50 respectively with board and residence

al Victoria Hospital, Dover —House Surgeon, unmarried. Salary £100 a year increasing with board, lodging and washing

sbury General Infirmary —Assistant House Surgeon unmarried. Salary at rate of £75 per annum, with apartments board and lodging

George's Hospital Medical School.—Lecturer on Insanity

John's Hospital for Diseases of the Skin 49 Leicester-square, W C —Superintendent. Salary £200 per annum

Pancras and Northern Dispensary 125 Euston-road.—Physician Accoucheur

Paul's Hospital for Skin and Genito-urinary Diseases Red Lion-square, W C —Honorary Assistant Surgeon.

toria Hospital for Children Tite-street Chelsea, S W —House Surgeon for six months Honorarium of £25 with board and lodging

Births, Marriages, and Deaths.

BIRTHS.

awner.—On Jan. 2nd at Hill House, Clay Cross the wife of Alfred Chawner L.R.C.P Lond M R.C S., of a son.

ll.—On Jan 7th, at Elstowe House, Itchen, Southampton, the wife of Edmund S Hall M.B Lond. M.R.C.S., L.R.C.P Lond. of a son.

MARRIAGES.

lteel—Hassall.—On Jan. 10th at St. Alfege, Greenwich, Cecil Edward Bulteel, Indian Medical Service, to Minnie Margaret Janet, youngest daughter of the Hon T H Hassall.

rdon Cruden —On Jan 8th at St Mary Abbot's, Kensington, William Gordon, M.D Lond., M R C P Lond., to Dora Mary elder daughter of Maj r Cruden

orris—Cullum —On Jan. 6th at Durban Natal, Captain J I Morris R A.M C to Alice, second daughter of J E. Cullum, F R.Met.Soc., the Valencia Observatory

N P —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents

THE BRITISH VIAVI COMPANY

We have received from a correspondent two abominable dirty little pamphlets issued by that coöperation of quacks which calls itself the British Viavi Company We have on sundry previous occasions expressed our opinion of these quacks notably in The Lancet of March 10th, 1900 (p. 742) There we commented upon certain facts which came out at an inquest held upon Feb 25th, 1900 by the coroner for East Sussex upon the body of a woman who had died while under treatment by the Viavi system. The jury handed in the following verdict: We wish to return a verdict of Death from natural causes we also think that the life of the deceased might have been prolonged had she been placed under properly qualified medical treatment and from the evidence brought before us we consider the Viavi company a fraud " So do we In another case heard before His Honour Judge Parry in the Manchester county court on May 17th, 1901, the Viavi Company had to pay £50 with all costs for breach of contract—i.e. for failing to cure Judge Parry remarked that it was a peculiarly wicked thing to take money out of people who were suffering from some ailment. He regretted that there should be people going about selling worthless remedies to poor women who knew nothing about their physical condition and thereby making 50 per cent profit In our opinion the company is composed of persons trading upon ignorance and appealing mainly to those who are always thinking about the sexual organs but it also professes to cure burns lumbago cross rupture," neuralgia, gall-stones and, in addition a delightfully comprehensive disease called internal trouble." The company issues a book of instructions called Viavi Hygiene, by Hartland Law M.D and H. E. Law F C.S " Of what university Hartland Law may be M.D we do not know but his name is not on the current Medical Register Neither does the name of H. E. Law F C S appear among the list of Fellows of the Chemical Society We cannot but think that it is time that the legislature stepped in to prevent the wholesale mischief which is daily and hourly caused by companies of quacks and by vendors of patent medicines. If they cannot be prosecuted for fraud they should at least be made to pay for a licence As we have said upon previous occasions no one may sell either tobacco or spirits without a licence and the licence implies no guarantee of the purity of the article sold. If a licence to be a quack were made to cost £500 per annum the trade would soon languish.

THE DESECRATION OF THE AMERICAN FLAG

We have received a copy of a strongly worded pamphlet concerning the degraded uses to which the law of the United States permits their national emblem to be put. We sympathise with the writers and agree that it is a matter of national importance that the national colours should be treated with respect, but legislation ought not to be necessary to enforce so obvious a sentiment as affectionate regard for the flag But certainly the citizens of the great republic are not very delicate in their feelings on the matter The writers point out a circumstance with which we are quite familiar in this office that miniature reproductions of the American flag are freely used as wrappers for itch ointments pile remedies, and other undignified nostrums. The following use of the flag a description of which we quote from the pamphlet, is new to us Since the birth of the American flag no more basely degrading insult has ever been offered to our national emblem than the suggestion of Speaker Henderson that the flag be used as a wrapper for American hams to the end of better advertising the hind-quarters of American hogs to the people of the United States and foreign countries." As a matter of fact, it is a nobler fate for bunting to enswathe a ham than a remedy for leucorrhœa but we can quite understand that many good American citizens think that both uses are degrading

MEDICAL MISSIONARY WORK.

To the Editors of The Lancet

Sirs —If your correspondent E. B " in The Lancet of Jan. 10th, p 144 will write to me I may be able to help him to obtain the information which he seeks.—I am, Sirs, yours faithfully

James Cheese, L.R.C.P Lond. M.R.C S Eng
Honorary Mission Secretary the Guild of St. Luke
58, Cornwall-gardens South Kensington, S W Jan. 10th 1903.

THE GEM" PURE WATER STILL.

This handy little apparatus for domestic purposes is quite simple in construction and in action. It consists practically of three parts a boiling chamber a steam space immediately above, and over this a compartment at the top which contains cold water The apparatus may be placed on a gas or oil stove or on the kitchen range. On the water below boiling steam escapes and impinges against the cold water container at the top. This container is shaped like a funnel upside down so that the water condensed on the sides of the funnel trickles into a circular channel just beneath from which the distilled water may be drawn off by means of a tap As long as there is cold water in the upper container and water being boiled in the lower container the process of distillation steadily proceeds We have used the apparatus with success and have found that the distilled water is free from mineral impurities We further ascertained that the distilled water was free from metallic contaminations Of course the water so obtained is sterilised The apparatus in very handy and consequently would be of great service when any suspicion of the purity of the ordinary drinking supply is entertained The still we examined was sent to us by the Gem Supplies Co Limited, of 121 Newgate-street London E C

THE EUTHERMIC COVERLET

WE have received a specimen coverlet of the above designation lined with material known as pinool " which in appearance resembles the wood fibre used for packing purposes We have submitted the material to certain tests and have found it to be decidedly non-conducting while it is porous and light. Further it possesses another quality desirable in the lining material of a coverlet—it is elastic. Under pressure the fibre is readily compressed and on withdrawing the pressure it returns to its original bulk. The fibre is straw-coloured and we found that on extraction with ether a green oily residue was obtained which gave off an aromatic smell resembling that of freshly sawn pine wood The material is said to be composed of a graded combination of vegetable fibres of which pine wood is the basis It seems well adapted for the purpose of lining a coverlet is comfortable to the touch and keeps the bed warm Besides it is a wholesome material with a faint and not unpleasing aromatic odour Unlike many materials for the purpose it does not readily harbour dust while it may easily be cleaned or replaced The specimen coverlet we examined was sent to us by the Sanitary Economic Association Limited of Station road Gloucester and the material was designed by Dr Francis Bond of that city

WANTED—TRANSLATION WORK

DOES any member of the medical profession require to have his book translated into German? It is possible that a medical publisher may require the services that are offered below by a correspondent who writes as follows: After having practised as a physician in Berlin for many years I am now living in England having retired from the practice of my profession I wish to use my leisure in translating some new and important English medical work into German We shall be happy to forward to our correspondent any communications that may reach us, which can be addressed either to us or to Translator "

CONSUMPTION SANATORIUM.

To the Editors of THE LANCET

SIRS—In reply to the inquiry of R L. G " which appears in THE LANCET of Jan 3rd p 78 I beg to state that a limited number of beds are set apart in this hospital for paying patients" at the following rates weekly—viz 30*s* for men and 25*s* for women Application for admission must be made on the prescribed printed form which I shall be happy to send to any person requiring one and as the hospital has been founded for the treatment only of cases in the incipient or early stages of the disease patients are before being admitted required to attend here for medical examination as to their suitability

I may add that ordinary " patients are admitted at the minimum rate of 7*s* weekly I am, Sirs yours faithfully

JOHN R ORPEN
Honorary Secretary National Hospital
for Consumption for Ireland

5 Leinster-street Dublin Jan 5th 1903

To the Editors of THE LANCET

SIRS—Replying to R L G " in THE LANCET of Jan 3rd, p 78, he might apply to Dr E L Colebrook Maitland Cottage, Peppard Common Oxon. I am Sirs yours faithfully

St Leonards-on Sea, Jan 9th 1903. J W RAWSON

ASEPTIC TEMPERATURE-CHART HOLDER.

A SPECIMEN of the chart holders which Messrs Maw Son and Sons of Aldersgate-street London E C have made at the direction of Dr Marcus M Bowlan medical superintendent St George-in the-East Infirmary London E and which are used in the lying in ward at that infirmary has been sent to us for inspection It consists of a sheet of aluminium with slits near each angle to receive the corners of the chart and two holes at the top for suspension on the wall with silk or silver wire. Dr Bowlan states that they are readily kept bright and have the additional merit of being easily sterilised by boiling in plain water

WE shall be obliged if the correspondent who inquired concerning the Nobel prizes will kindly communicate his address which has been mislaid.

◆

M.B Cantab—Our correspondent's contribution to the controversy arrived at a time when our columns were very overcrowded He will see however that we in no way suggest that the reform in the preliminary examinations of the University of London should mean that the standard should be lowered It is hoped that the student's path will be made smoother by relieving him of a multiplicity of examinations and the necessity of obtaining a superficial knowledge of subjects which he will never pursue as genuine studies. It is not proposed that the degrees of the University shall be cheaper

J R T—(*a*) The M B degree of the University of Sydney is registrable in the Colonial List. (*b*) There are many holders of foreign or colonial degrees practising medicine in this country but their place on the Register is due to the fact that they possess British registrable titles Complete information on the point will be found in the tables prefixed to the Medical Register (*c*) As a rule the tests of one examining body are not accepted by other examining bodies but in any particular case it might be well to make inquiries from the Medical Registrar

M.B B C—Our opinion is much the same as our correspondent's. He will find in our columns and in the publication "The Battle of the Clubs " frequent examples of the system which he mentions and which he rightly reprobates. A recent decision of the General Medical Council strongly condemns the practice of house-to-house touting. No medical man should work for a club employing this method, and still less should any medical man employ it himself

H H B—We are obliged to our correspondent for forwarding the powder an examination of which will be made, and, if thought necessary the results will be published in our columns.

quator—' Diseases of the Lungs " by Dr Kingston Fowler and R. Rickman Godlee

ERRATUM.—The publisher of Practical Physiology " by Dr A P Beddard and other writers reviewed in THE LANCET of Dec. 2[illegible] should have been stated as Mr Edward Arnold not Edwin Arnold.

Medical Diary for the ensuing Week.

SOCIETIES

TUESDAY (20th).—CHELSEA CLINICAL SOCIETY (Jenner Institute of Preventive Medicine Chelsea gardens Grosvenor road, S.W.).—8.30 P.M Discussion on the President's Opening Address on Child-bearing in Chronic Heart Disease

PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P M Bacteriological Section Dr Klein: A New Pathogenic Diphtheroid Bacillus.—Mr A Foulerton and Dr V Bonney: A Diphtheroid Bacillus isolated from Two Cases of Puerperal Fever.—Dr L Barlow A Higher Mould Fungus isolated from a Case of Multiple Granulamatous Tumours.—Mr A Foulerton and Dr A. M Kellas: The Action on Bacteria of Currents or Discharges of High Tension and Rapid Frequency.—Dr C G Seligmann: The

Inhibitory Effect on Bacterial Growth of the Viscid Exudate from Tabetic Joints &c.—Dr Klein: Demonstration of Specimens from Plague in Rats.

DNESDAY (21st).—ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Great George-street, S W.).—7.30 P.M. Ordinary Meeting 7.30 P.M. Report of the Council. Election of Officers and Council for the ensuing year Address:—Mr W H. Dines (President) The Method of Kite-Flying from a Steam Vessel and Meteorological Observations obtained thereby off the West Coast of Scotland

OYAL MICROSCOPICAL SOCIETY (20 Hanover-square, W)—8 P.M. The President will deliver his Annual Address.

URSDAY (22nd).—NEUROLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W).—8.30 P.M. Annual Meeting Dr J N Langley The Autonomic Nervous System (Presidential Address)

IDAY (23rd).—CLINICAL SOCIETY OF LONDON (20 Hanover-square, W)—8 P.M. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 P.M. to 9 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

NDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C.)—4 P.M. Dr A. Whitfield: Clinique. (Skin.) 5.15 P.M. Dr K. Grube Hydro-therapeutics and Balneo-therapeutics.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.)—5 P.M. Dr A. Saunders: Broncho-pneumonia and its Treatment in Children.

ESDAY (20th).—MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street, W C.)—4 P.M. Sir W H. Broadbent: Clinique. (Medical.) 5.15 P.M. Dr P Stewart Cranial Nerve Paralysis.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road W)—5 P.M. Mr. A. Baldwin: Treatment of Some Injuries and Emergencies.

UNIVERSITY OF LONDON (Physiological Laboratory)—5 P.M. Dr W D Halliburton On the Chemistry of Muscle and Nerve. (Lecture on Advanced Physiology)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen square, Bloomsbury)—3.30 P.M. Dr R. Russell: Anatomy of the Spinal Cord.

EDNESDAY (21st).—MEDICAL GRADUATES COLLEGE AND POLYCLINIC (22, Chenies-street, W C)—4 P.M. Mr J Berry: Clinique. (Surgical.) 5.15 P.M. Mr H. Pinch Inflammation and Repair

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W)—5 P.M. Dr McAdam Eccles Surgical Anatomy

HURSDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C)—4 P.M. Mr C B Keetley: Clinique. (Surgical.) 5.15 P.M. Dr W S Colman Infantile Scurvy

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W)—5 P.M. Mr Paget Surgical Cases.

UNIVERSITY OF LONDON (Physiological Laboratory)—5 P.M. Dr T G Brodie On the Circulation. (Lecture on Advanced Physiology)

CHARING CROSS HOSPITAL.—4 P.M. Dr W Hunter: Demonstration of Pathological Cases. (Post-Graduate Course.)

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W C)—4 P.M. Dr Baumann Pathological Demonstration.

RIDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W C.)— P.M. Dr H. Tilley: Clinique. (Throat.) 5.15 P.M. Dr H. W G MacLeod House Ventilation and Drainage.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road W)—5 P.M. Dr Beddard Epilepsy

UNIVERSITY OF LONDON (Physiological Laboratory)—5 P.M. Dr A. D Waller: On the Action of Anæsthetics and Narcotics. (Lecture on Advanced Physiology)

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen square, Bloomsbury)—3.30 P.M. Sir V Horsley: Surgery of the Nervous System.

EDITORIAL NOTICES

IT is most important that communications relating to the ditorial business of THE LANCET should be addressed xclusively To THE EDITORS, and not in any case to any entleman who may be supposed to be connected with the ditorial staff. It is urgently necessary that attention be iven to this notice.

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this office

Lectures, original articles, and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed To the Sub Editor

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed To the Manager*

We cannot undertake to return MSS not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. II. of 1902, which was completed with the issue of Dec 27th, and the Title-page to the Volume, were given in THE LANCET of Jan. 3rd.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready Cloth gilt lettered, price 2*s.* by post 2*s* 3*d*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices 423, Strand, W C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM				TO THE COLONIES AND ABROAD			
One Year	£1	12	6	One Year	£1	14	8
Six Months	0	16	3	Six Months	0	17	4
Three Months	0	8	2	Three Months	0	8	8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON ENGLAND

A Clinical Lecture

ON

TUMOURS OF THE BLADDER

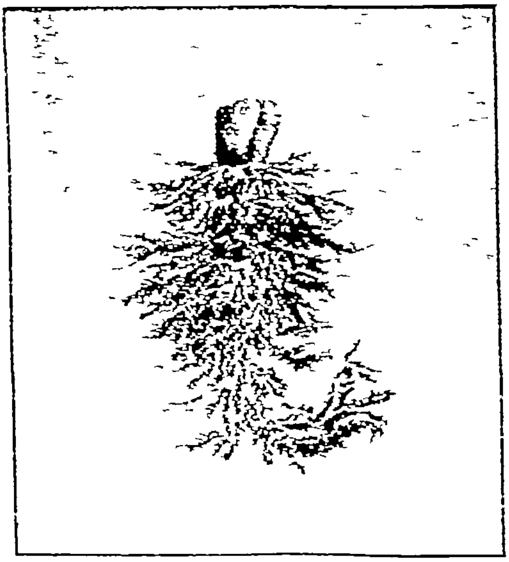
Delivered at the Medical Graduates College and Polyclinic on Sept 10th 1902,

BY P J FREYER, M.A., M.D, M.CH R.U.I.,
SURGEON TO ST PETER'S HOSPITAL EXAMINER IN SURGERY AT THE UNIVERSITY OF DURHAM.

GENTLEMEN,—Tumours of the bladder may occur either as *primary* or *secondary* growths. The former alone are of practical importance to the surgeon and in the following remarks I shall deal exclusively with them.

Tumours of the bladder, like tumours in any other region of the body, may be classified most conveniently according to the tissue from which they have their origin or of which they are composed (1) epithelial tumours, (2) connective tissue tumours, (3) dermoids, and (4) cysts. Those of the latter two groups are rarely found in the bladder and require merely passing notice. New growths of the first group are those most frequently encountered and they demand particular attention. Of these, the most important—as most common and most amenable to treatment—is the papilloma, of which there are two typical forms (1) villous papilloma and (2) fibro-papilloma.

FIG 1



Papillomata of the bladder have their origin apparently in an overgrowth of the normal mucous membrane and are analogous to the cutaneous warts The type of papilloma most frequently met with is the pedunculated "villous papilloma" (Figs 1, 2, 3, and 4) which consists of a fleshy mass, varying generally in size from that of a cherry to that of a walnut, attached to the bladder wall by means of a pedicle and covered partially or wholly by villous processes or papillæ, from which the tumour derives its designation If we immerse a typical specimen of this kind in water immediately after removal and examine it we find that the pedicle terminates in an expansion named the "core" or "framework" which is clothed by villi projecting from its surface and giving the whole a shaggy, flocculent appearance of greyish white colour If we then lift it out of the water and examine it in air we find that the villous processes have collapsed and adhere, the tumour resembling a mass of wet grey velvet or a miniature deck mop Viewed through the cystoscope in the bladder before removal the villi, or fimbriæ when long, influenced by the artificial currents set up by the movements of the instrument, are seen to wave about in the fluid, the growth as a whole presenting a bright pink appearance, of rare beauty sometimes, due to the blood circulating in the villi being visible through the almost translucent structure. Occasionally hæmorrhagic spots, or even ulcers, may be seen, the result of contusions

Directing attention now to the component parts of a papillomatous growth, we find that the pedicle may be either cylindrical or somewhat flattened. It varies in length, as a rule, from a quarter of an inch to one inch, but occasionally attains to several inches It varies in thickness from that of a slender thread to that of a cedar lead-pencil, the very fine variety being rare. This pedicle is composed mainly of connective tissue, interspersed with which are found unstriped muscular and elastic fibres derived from the submucosa, the surface being covered by epithelial cells similar to those found in the bladder Vessels and nerves pass through its axis. The pedicle is attached to the mucous covering of the bladder alone, and when pulled on the latter is raised off the muscular coat in pyramidal fashion. There is no infiltration of the adjacent mucous membrane or submucous tissue—a point of vital importance in distinguishing this growth from those of a malignant type.

The structure of the core, or body of the tumour, is similar to that of the pedicle, of which it is, indeed, merely an expansion Frequently the framework is merely a prolongation of the pedicle, covered with tufts of villi, and occasionally there is little or no body, the tufts of villi springing directly from the end of the pedicle, the whole resembling a pollard tree. The body, again may be lobulated, composed of several distinct, more or less rounded masses, each covered by short thick set villi, the whole presenting a cauliflower like appearance Indeed, innumerable varieties of this tumour, as regards shape, number, and attachment of the villi, are found.

The villosities covering the surface of the growth vary much in length and shape. Some are so short as to be recognisable only by a hand lens. These short, thick, compactly set villi may give the tumour a velvety appearance. Other long and slender fimbriæ may reach a length of one or two inches and are more sparsely arranged. Between these extremes all varieties of villi are found. They may spring from the tumour as simple thread-like cylinders or as miniature flattened blades of grass Some bifurcate, others digitate, or they may branch and rebranch like a tree Portions of the surface of the tumour may be devoid of villi, giving it a bald appearance in patches. Hæmorrhagic spots or ulcers may be present from traumatism, and deposits of phosphates may take place on its surface, particularly on, and in the vicinity of, the ulcers Microscopically an individual villus is found to be composed of delicate connective tissue, covered by layers of columnar epithelial cells, and traversed by a capillary loop

FIG. 2.

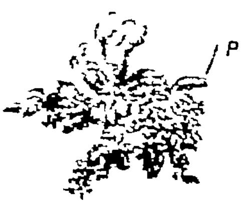


FIG 3.

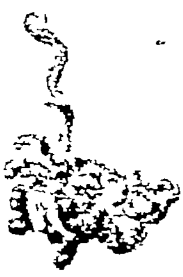

FIG 4

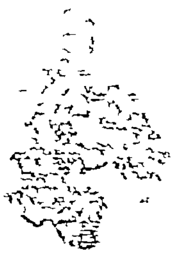


of blood vessel. Isolated fibres of unstriped muscle, continued from the core are sometimes found entering the base of the villus for a short distance.

When a tumour is attached to the bladder wall by means of a pedicle it is termed "pedunculated," and this is the most common variety It may, however, spring from the mucous membrane by a broad base, without the intervention of a pedicle, when it is termed "sessile." If the base or attachment of the tumour be contracted, forming a neck, the term "subsessile" is applied. Sometimes the simple villi spring directly from the mucous covering of the bladder, either in clumps or scattered broadcast over an extensive surface without the intervention of any body or core—a condition which may be described as "diffuse" papilloma. When the villi are arranged on ridges or crests of mucous membrane the term "coronoid" is sometimes employed

Though papillomata may arise from any portion of the mucous membrane of the bladder, except, perhaps, the trigone, they are most frequently found in the vicinity of the ureteral openings In my own practice I have found them most commonly attached to the bladder wall to the outside and in front of the ureteral orifices Instances of benign papillomata growing solely from the trigone are extremely rare, if ever found I have not met with an instance of this kind in my own practice But springing from the mucous membrane close to the trigone the base of the tumour not infrequently encroaches by growth on that area. The exemption of the trigone from growths of this nature is attributed to the fact that the mucous membrane of this area is firmly bound down to the subjacent muscular coat without the intervention of any loose areolar tissue. Laxity of the mucous membrane seems to be essential to the development of these soft villous tumours. Papillomata spring occasionally, though rarely, from the inner orifice of the urethra.

Papillomata, whether sessile or pedunculated, vary in size from that of a pea to an enormous mass almost filling the bladder The largest which I have removed was of the size of an orange and was attached to the outer edge of the left ureteral orifice by a pedicle an inch long and as thick as a goose quill. This was in a patient sent by Dr J W Erskine of Chelsea, who was present at the operation in June, 1897 The symptoms, which were not severe had existed for only two years. On the other hand, a papilloma may be of extremely slow growth and, though small in size, may give rise to very grave symptoms. On June 20th, 1899, I removed a pedunculated papilloma of the size of a cherry (Fig 3) from a patient, aged 36 years, sent by Dr J J C Constable of Kennington Park This gentleman had suffered from hæmaturia for 18 years, and at the time of operation was extremely anæmic from constant loss of blood There has been no recurrence and the patient is now in sound health.

Papillomatous tumours occur singly in the vast majority of cases When multiple the number, as a rule, does not exceed three or four Occasionally numerous growths are found scattered over the surface of the bladder In cases of multiple growth there is generally a largish tumour with one or more subsidiary growths It has been suggested—without any tangible proof, however—that the subsidiary growths are derived as seedlings from the main growth

There are instances on record of spontaneous detachment of a pedunculated papilloma. This accident probably occurs through spasmodic contraction of the bladder on the tumour, thus rupturing the pedicle, or through twisting of the pedicle on itself, giving rise to strangulation and death of the tumour owing to the cutting off of the blood supply Papilloma is most frequently found between the ages of 25 and 50 years, though it may occur in childhood or in old age Males are more frequently affected than females.

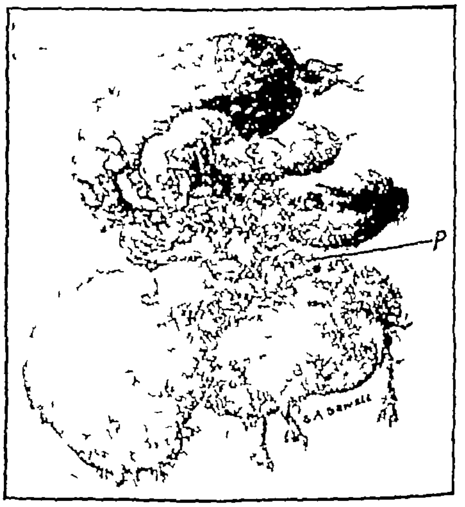
A pedunculated growth may from time to time be carried during the urinary flow against the neck of the bladder, or even into the prostatic portion of the urethra, and block the passage, thus giving rise at first to hypertrophy to overcome the resistance but eventually to atrophy and pouching of the walls of the bladder Cystitis is not an infrequent sequela of the presence of a tumour in the bladder A growth, whether pedunculated or sessile, growing close to, or from, the margins of a ureteral opening may block the canal and thus give rise to dilatation of the ureter with other backward pressure changes resulting in destruction of the corresponding kidney

Papillomata are occasionally found devoid of elongated fimbriæ, consisting of more or less dense fleshy masses covered by extremely short thick set papillæ, giving the general contour of the tumour a more or less smooth, though sometimes lobulated, appearance. These are termed "fibro-papillomata." Structurally they are composed of the same elements that enter into the villous papillomata but more densely arranged. Tumours of this type are, as a rule, sessile, slower in their growth, and do not attain the large size of the fimbriated papillomata.

When a growth is recognised by the cystoscope to be covered by villi we must not at once come to the conclusion that it is necessarily of a benign type, for malignant tumours are sometimes clothed with villi and these growths may occur as more or less pedunculated tumours. It is characteristic of a benign growth that there is no hardness about its base or pedicle and that the mucous membrane in its vicinity is soft and devoid of infiltration The existence of hardness of the base or infiltration in the adjacent mucous membrane at once arouses suspicions of malignancy

Intermediate between the typically benign papillomata and malignant tumours comes a type known as "transitional" Tumours of this nature on first removal present all the appearances of simple growths, both macroscopic and microscopic, save that the ground work is more dense and irregular, and the "presence in it of irregularly shaped cells which do not belong to normal tissue on the one hand, or to distinct new growths on the other" (Heneage Gibbes). Tumours of this type have a tendency to recur after removal, becoming more and more fleshy, with infiltration of the surrounding mucous membrane on each recurrence, the patient eventually dying from undoubted cancer A typical case of this kind occurred in a lady, aged 54 years, sent to me by Mr W Armstrong of Buxton The tumour (Fig. 5), which was sessile and of the size of a large walnut, showed no signs of malignancy on first removal but it recurred, and after being four times removed, together with the adjacent mucous membrane from the vicinity of the left ureteral opening, eventually recurred as carcinoma on the right side of the bladder, to which the patient succumbed

FIG 5.



Adenomata rarely if ever occur in the bladder, as might be expected, seeing that it is doubtful if true glands exist in its mucous membrane. In the few instances that have been placed on record by writers the tumours were found in the vicinity of the neck of the bladder There is nothing in the descriptions of these cases to indicate that they were other than adenomata of the prostate, projecting into the bladder. In my recent practice of total extirpation of the prostate I have found that barnacle like adenomatous outgrowths of the prostate may appear in the bladder at a considerable distance from that organ connected therewith by long, slender, fibrous pedicles, or 'runners," lying beneath the mucous membrane. These might easily be mistaken for adenomatous tumours of the bladder

Epithelioma, or squamous celled cancer, as a primary disease of the bladder is not uncommon, ranking next in frequency of occurrence after papilloma It occurs in the latter half of life, being extremely rare before the age of 40 years.

t has its origin in the mucous membrane and may commence as a warty outgrowth, a simple fissure, or an irregular lcer. In whatever form arising the disease advances rapidly, preading over an extensive area of mucous membrane and nvading the underlying tissues. Large, elevated, fungating masses and hard nodules soon project into the bladder, loughs are thrown off, accompanied by fœtid discharges, and life is rapidly destroyed through loss of blood, infection of the lymphatic system, as well as from the pain and constant distress due to frequency of micturition and perpetual straining, the bladder being unable to retain more than a small quantity of urine. The glands affected are the pelvic, retro-peritoneal, inguinal, and lumbar. Secondary deposits in other organs are, however, rare. As already stated, a cancer may have villi projecting from its surface; it is then termed a "villous carcinoma." In the later stages of the disease an epithelioma of the bladder may ulcerate into the bowel, a fistula being thus established and fæces passing through the urethra and urine by the rectum. Or it may appear in the groin, causing pressure on the nerves and vessels and giving rise to severe pain and œdema in the corresponding lower limb. It may make its way through the sacro-sciatic foramen and involve the sacral nerve.

Tumours of the connective-tissue type are of rare occurrence in the bladder.

1. *Fibroma.*—This tumour, though nearly allied in structure, must not be confounded with the fibro-papilloma already described. The latter has its origin in the mucous membrane, whereas the fibromata spring from the submucosa or fibrous tissues in the muscular coat and have the mucous membrane simply stretched over, but not involved in, the growths. The fibromata are rarely pedunculated, being usually sessile, or subsessile, polypoid outgrowths, and they are usually single. They are almost invariably found in adults. As a rule, they spring from the base of the bladder, but the only instance of this tumour that I have met with in my practice sprang from the summit of the bladder near the ifice. It was of the size and shape of the adult thumb d hung down over the neck of the bladder, obstructing the inary flow. Fibromata are composed of adult connective ssue, with a few elastic fibres and fusiform cells interspersed. They are smooth-surfaced and on section present a hite, glistening appearance.

2. *Myxoma.*—The myxoma, closely allied to the fibroma, the soft, gelatinous, mucous polypus, similar in structure the nasal polypus except that the covering epithelium is quamous. It is, as a rule, composed of a soft, gelatinous, roteid substance identical with that found in the umbilical rd, but some varieties are harder, containing a considerable admixture of normal fibrous tissue. Growths of this pe occur only in young children and may be either sessile pedunculated. They are generally multiple.

3. *Myomata.*—These are composed mainly of unstriped uscle fibres, interspersed with scanty fibrous tissue. They re of extremely rare occurrence. They have their origin in e muscular coat of the bladder and may project inwards rming "intra-vesical" sessile or pedunculated growths, ely covered by the mucous membrane. They may remain interstitial" or project outwards from the surface of the ladder, covered by the peritoneum, forming "para-vesical" umours. When growing inwards they rarely attain a large ze and are easily enucleated. The largest intra-vesical rowth of this kind on record, as far as I am aware, ccurred in my practice. The patient and tumour were hown at a clinique in the Medical Graduates' College and olyclinic on Jan. 15th, 1902. The details of the case have een already reported[1] and briefly are as follows.

A married female, aged 24 years, had suffered from hæmaturia, increased frequency of micturition, and stoppage of he flow of urine for four years, with a tumour gradually ncreasing in size and eventually projecting into the anterior ortion of the vagina. When she first came under observation in October, 1901, the tumour was as large as a cricket all. It projected into the vulva and was covered by the anterior wall of the vagina which was pushed down before it. With a finger in the vagina and a hand placed above the pubes the tumour could be rolled about a fixed point in the left half of the pelvis. The patient had to push it up from the vulva before micturition, which sometimes required the catheter. Cystoscopy revealed a large, smooth, globular sessile tumour of the bladder, with large veins coursing over it, springing from the trigone and left side of the base of the bladder and in front of the left ureteral opening. On Oct. 30th, 1901, I opened the bladder suprapubically and snipped the mucous membrane over the tumour which was rapidly and easily enucleated. The patient made a rapid recovery, leaving St. Peter's Hospital within a month. She is now in excellent health, untroubled by any urinary symptom. The tumour weighed nine ounces and was found on microscopic examination to be a pure myoma.

4. *Sarcoma.*—This is the most common of the tumours of the connective-tissue type found in the bladder, but even this is rare in comparison with epithelial growths. It may occur at any age, arise in any part of the bladder, and is invariably sessile. It occurs as a smooth, dense, rapidly growing tumour involving the entire thickness of the bladder wall. The round- and spindle-celled varieties are those most frequently found.

Other tumours of the connective-tissue type are of extreme rarity in the bladder.

SYMPTOMS AND DIAGNOSIS.

Hæmaturia is the most important, as it is almost invariably the earliest, symptom in all forms of tumour of the bladder. If a patient consults you for hæmaturia coming on spontaneously without apparent cause you should at once suspect the presence of a vesical growth, and if the hæmaturia be painless the growth will in all probability turn out to be benign. The hæmaturia is, as a rule, intermittent, the attacks lasting from one to several days and completely ceasing in the intervals. In the early history of the disease the intervals may be prolonged, weeks or even months elapsing before a recurrence of bleeding takes place, but as the disease progresses the attacks of hæmaturia increase in frequency and intensity. Eventually the urine may never be quite free from blood, though at times the bleeding will be more profuse than at others. The urine is not uniformly mixed with blood, as in hæmorrhage from the kidneys. During the act of micturition it will be noticed that the earlier portions of the urine will be clear and free from blood—at least, to the unaided eye—and that the stream gets gradually deeper in colour till eventually pure bright blood is passed. Occasionally the urine may be tinged with blood even at the commencement of micturition, but the tinge gradually deepens and some pure blood is invariably passed at the end. Clots are frequently present—dark and irregular masses contrasting with the worm-like clots found in connexion with renal hæmorrhage. The hæmaturia is generally independent of position and motion, occurring as frequently when the patient is sitting or lying down as when getting about, thus presenting a marked contrast with the bleeding attendant on stone, which is always worse when the patient takes exercise. Profuse hæmaturia is rare in connexion with stone, whereas with tumour it is the rule. The extent and frequency of the bleeding do not bear any proportion to the size of the tumour. A growth may attain a very large size before it is attended by hæmaturia and quite a small growth, as in the case of Fig. 3, may involve profuse and constant bleeding endangering life. Soft growths, and particularly those clothed with villi, bleed more freely than the dense and bald varieties, and pedunculated more than sessile growths.

Increased frequency of micturition occurs sooner or later with all vesical growths, and once it sets in it never disappears till the tumour is removed. It is most marked in cases of growth situated near the neck of the bladder. Exceptionally it is the initial symptom and may exist for lengthened periods before hæmaturia supervenes. In the case of a lady aged 53 years whom I attended in consultation with Dr. W. H. Bourke of South Kensington, increased frequency of micturition (attended latterly by some scalding) had existed for two years, but there had never been any hæmaturia. The cystoscope at once revealed a pedunculated villous growth of the size of a large strawberry springing from near the right ureteral opening, which I successfully removed suprapubically. Two symptoms—viz., increased frequency and pain—are not uncommon in women who have passed middle life, and are, as a rule, due to pressure of the womb on the bladder. I was inclined to attribute the symptoms in this case to this cause, and it was only after Dr. Bourke had assured me that he had satisfied himself that this was not the case that I consented to examine the patient cystoscopically. This and other cases in my practice have taught me a lesson—viz., that when these symptoms are due to no apparent cause the cystoscope should be employed, even when hæmaturia is absent. The hæmaturia and frequency of micturition due to non malignant growths are in the earlier stages of the disease, as a rule, unattended by pain, but in malignant growths pain is present almost from the beginning

---

[1] Journal of the British Gynæcological Society, vol. i., 1902.

Pain is nearly always present in the later stages of all kinds of tumour, due to a variety of causes, such as cystitis, passage of clots, blockage of the urethra by the growth, or pressure of the growth as it enlarges on the nerves Sessile and infiltrating growths are more painful than pedunculated ones The pain will, as a rule, be referred to the perineum, or as shooting along the whole urethra, in contrast with the pain of stone which is referred to the end of the penis and that of prostatic disease which is usually felt supra pubically

Retention of urine, partial as a rule but occasionally complete, may occur, due to clots, fragments of tumour tissue, or even a pendulous growth itself blocking the urethra.

With these symptoms we may find detached *shreds of tumour tissue* in the urine, microscopic examination of which may give a clue to its nature, always bearing in mind that benign villosities may grow on a malignant base.

Pus in the urine will be present when cystitis occurs. This is rare in benign growths, particularly in the earlier stages, unless from septic instrumentation It frequently occurs early in malignant growths and is always present in their later stages as a terribly painful and distressing complication.

Not infrequently the inflammation from cystitis extends along the ureters to the kidneys, giving rise to pyelitis, nephritis, and suppuration of the kidneys. Blockage of a ureter by the tumour may give rise to hydronephrosis, blockage of both ureters may cause anuria and uræmic symptoms. Rectal examination in the male and vaginal in the female will aid us in forming a diagnosis, but only in cases of malignant growths in which the base of the bladder may be felt nodulated and unyielding from infiltration of its walls, or in the case of large fibrous or myomatous growths arising in this position A papillomatous benign growth, whether sessile or pedunculated, will not be felt per rectum. When the tumour attains a large size, whether malignant, fibrous, or myomatous it may be felt bimanually by placing one hand above the pubes and a finger of the other hand in the rectum or vagina

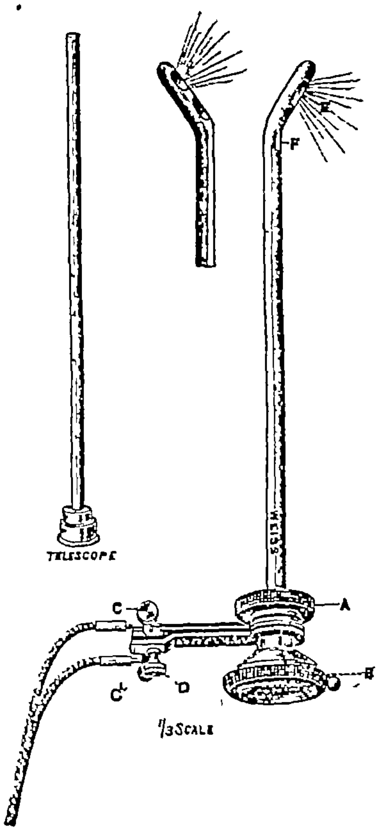
With the presence of the symptoms described a sound will probably be employed to ascertain if a stone be present in the bladder No definite information as to the presence of a growth can be obtained by this means, though a sensation as of the existence of an undefined soft, or even tough mass in the bladder, and limitations of the movements of the instrument, may lead us to suspect the presence of a tumour

Washing out the bladder by means of an evacuator and catheter and the introduction of a lithotrite with a view to detaching and bringing away portions of the tumour for examination were formerly employed, but such methods have now been abandoned since the introduction of the electric cystoscope, which provides us with a scientific and accurate means of arriving at a definite diagnosis as to the presence of a tumour as well as to its size physical characters position, and form of attachment to the bladder wall, as also to a fairly accurate forecast as to its nature.

CYSTOSCOPY

Leiter's cystoscope (Fig 6), which is the instrument now almost universally employed for illumination of the bladder, consists of a metal tube, bent near the end at an obtuse angle, resembling somewhat a bladder sound in shape. The bent portion, or beak, consists of a cylindrical cap which can be screwed on and off the shaft at the elbow of the instrument and is furnished with an oval rock crystal window (E) on the upper or concave aspect. Encased in this metal cap and situated opposite the window is a miniature electric lamp connected with the end of the shaft, through which, inside the metal tube run insulated wires to the connecting screws (C, C′) By the detachable nature of the beak the lamp when defective, can be replaced by a new one in a few seconds. The arrangement as a whole forms a water tight compartment for the lamp which illuminates the bladder through the glass window without coming in contact with the fluid in which it must necessarily burn, in order to protect the bladder walls from injury In the shaft, just above the elbow, is inserted a glass prism (F) by which the rays of light from the bladder are refracted along a telescope inserted in the shaft and capable of being removed for the purpose of being cleaned or for use in another instrument. The rim of the ocular end (B) through which the observer looks is covered by a thin plate of ebonite to prevent shock in case of contact of the eyebrows with the cystoscope. A knob (B) on the edge of the ocular end indicates the aspect of the bladder towards which the beak and prism are directed from time to time. By means of a screw (D) the circuit can be closed and opened. This screw, together with the connecting screws, are carried on a rotatory plate, or swivel, so that with the finger and thumb of one hand placed on the cylinder (A) the beak of the instrument can be revolved so as to bring any part of the bladder into view, while the connecting cords remain in position, being held downwards by the other hand.

FIG 6



The standard cystoscope employed for adult males is in size 22 of the French scale and with this a surface of three or four inches in diameter can be seen at one time. Cystoscopes are specially made larger, up to 40 of the French scale, for employment in females, giving a more brilliant illumination and bringing a larger surface into view at the same time They are also constructed smaller for children, but the diminution in thickness of the instrument involves a rapid narrowing of the field of vision, as well as a darkening of the picture presented to the eye. Formerly, a second instrument was employed, with the window on the under aspect of the beak and a simple pane of glass in the convexity of the elbow, for the purpose of viewing the base of the bladder, and particularly the trigone, but this is now little used, as since the introduction of the swivel arrangement referred to all portions of the bladder can be brought into view by the instrument already described.

In cystoscopy the patient is most conveniently examined in the supine position on an ordinary operating table, with his buttocks raised on a hard cushion and his legs slightly separated. The lithotomy position may also be employed and is, perhaps, best for females. As a rule a male requires an anæsthetic for careful and thorough examination, though sometimes this may be dispensed with, the urethra being locally anæsthetised by means of cocaine. An anæsthetic is rarely required for females who, as a rule, feel no pain or inconvenience from the examination.

A clear fluid medium is, of course, necessary to obtain a satisfactory view of the bladder and its contents. The best medium is the patient's urine, provided this be sufficiently clear, and this can frequently be attained by keeping the patient in bed for a few days previously to examination and directing him to retain his urine for three or four hour beforehand if possible But if the urine be clouded with blood, pus, or muco-pus it will be necessary to wash out the bladder through a soft catheter by means of warm boric lotion or boiled water This should be done very slowly and gently so as not to excite fresh bleeding When the fluid flows quite clear from six to eight ounces should be introduced and left in the bladder Glycerine should be employed for lubricating the catheter instead of oily substances which would adhere to the windows of the cystoscope and obscure the view Some diseased bladders resent the introduction of more than three or four ounces of fluid even under deep anæsthesia but even this quantity may suffice to give us important information.

The cystoscope should be examined beforehand to ascertain that it is in working order and that the illumination is of the proper strength It is rendered aseptic by thorough washing with soap and warm water and immersion in warm carbolic lotion. It is then smeared with glycerine and introduced like an ordinary sound, very slowly and gently, to avoid even the slightest bleeding if possible, and pushed as far into the bladder as the rim will permit. Care should be taken that the light is well switched off before introduction of the cystoscope. The observer's eye is now applied to the ocular end and the light is switched on, when the bladder will suddenly appear illuminated. The beak being directed upwards, the first portion of the bladder that comes into view is the apex, and if a growth has its origin in this position, which is rare, it will be observed at once. If the medium be quite translucent the surface of the bladder will be seen as clearly as if it were exposed to broad daylight, corrugated more or less according to the quantity of fluid introduced, greyish white, with the minute blood vessels visible the general appearance recalling that of the retina as seen through the ophthalmoscope.

A methodical survey of the bladder is now made. It is best in the first instance to bring the ureteral opening on one side into view and then that on the other side—small slit-like openings, placed obliquely, directed downwards and inwards, at the extremities of the inter ureteral bar These objects afford landmarks from which we take our bearings in surveying the bladder In the vast majority of instances tumours if present will be found in their vicinity The cystoscope should then be withdrawn till the prism approaches the neck of the bladder, the collar of which will be recognised by its dark crimson colour and smooth rounded edge, and a complete revolution of the beak slowly made in this position. Similarly the fundus is examined by pushing the cystoscope in as far as the rim will permit and revolving it in this position The beak must not be allowed to remain in contact with the bladder wall at one point for more than a few seconds, for fear of scorching the mucous membrane, but kept constantly on the move, the light being periodically switched off for a few seconds to cool the lamp Before withdrawal of the cystoscope from the bladder the light should be switched off for half a minute to avoid burning the urethra. To make assurance doubly sure in this respect I always detach the connecting cords from the instrument before its withdrawal The fluid is then drawn off by a catheter when the examination is completed

It is impossible in a lecture of this kind to teach all the details necessary for a successful cystoscopic examination and a correct appreciation of the appearances observed These can only be acquired by practice and are best learnt under the guidance of an experienced cystoscopist It must be remembered that objects are observed reversed in position, and greatly magnified when close to the prism. The current is supplied from a small battery an accumulator, or from the main through the medium of a transformer

Should there be bleeding during the examination we may be unable to obtain a clear view or merely for a short time, so that it may be necessary to withdraw the cystoscope and to wash out the bladder once more till the fluid runs clear Should the bleeding still continue it will be necessary to postpone the examination to a future date, the patient being kept quiet in bed in the meantime and the re-examination undertaken when bleeding has quite ceased

Apart from the diagnosis of tumours of the bladder, which may be regarded as the chief function of the cystoscope, it may be well to state here that this instrument is now employed in clearing up the nature of many other obscure diseases of the urinary track—viz., (1) hypertrophy of the prostate to ascertain the extent and nature of the outgrowth in the bladder, (2) encysted calculus of the bladder (3) tuberculosis of the bladder, (4) chronic ulcer of the bladder, (5) foreign bodies in the bladder, (6) hæmorrhage or discharge of pus from one or both ureters in various diseases of the kidneys, (7) stone impacted in the lower end of the ureter in its descent from the kidney, and (8) to ascertain the conformation of the ureteral openings in certain diseases of the kidneys, &c.

TREATMENT

Though the hæmorrhage, pain, and other symptoms attendant on tumours of the bladder may be temporarily held in check by astringents and narcotics, administered internally or locally applied, the only line of treatment that offers a prospect of permanent relief consists in complete removal of the growth. Following the lead of Sir Henry Thompson, for some years after 1880 surgeons generally accomplished this by means of perineal cystotomy I myself have removed several tumours through this route with considerable success But this method has now for several years been practically abandoned in favour of operation through the suprapubic route, which possesses the advantages that not only can a more thorough survey of the bladder be made in this way by the finger, but by means of an electric forehead light and appliances that will presently be described the interior of this viscus and its contents can be brought into view so that the tumour can be removed with greater precision than by the perineal route.

Suprapubic cystotomy—The patient, previously prepared by shaving the pubes and applying an antiseptic compress over the pubes and hypogastrium, is placed on his back on the operating table The Trendelenburg position advocated by some surgeons is quite unnecessary A rubber catheter is introduced the urine is drawn off, and the bladder is thoroughly washed out with warm boric lotion by means of a six or eight-ounce syringe. Petersen's bag for inflating the rectum previously to distending the bladder with a view to raising the peritoneum out of the way was formerly much in vogue I constantly employed it for some years after its introduction, but have now entirely abandoned this adjunct to the operation as unnecessary for the purpose for which it was introduced and attended by inconvenience and considerable danger It distorts the bladder out of shape is liable to lacerate the mucous membrane of the bowel and cases are on record where rupture of the bladder attended its employment. The bladder is simply distended with from 10 to 14 ounces of warm boric lotion and the catheter is left *in situ* with a clip forceps applied to prevent the lotion flowing out.

An incision of from two to three inches in length, according to the stoutness of the patient, is now made in the median line of the abdominal wall terminating at the symphysis pubis This incision is carried at once through the skin and subcutaneous tissues as far as the muscles Any bleeding vessels are clamped and the incision is continued either between the recti muscles or through one of them till the prevesical fat comes into view The point of the forefinger is then introduced through the wound and passed down close behind the symphysis, the prevesical fat is scraped through by the finger nail till the bladder is reached, and is drawn upwards off the bladder for the whole length of the wound—the peritoneum if extending low down being pushed up before it. As a rule, the peritoneum is not seen, being covered by the fat

The bladder will now have come into view presenting a greyish glistening appearance, with purple gorged, tortuous veins coursing in its wall and visible on its surface. The scalpel is at once plunged through the bladder wall in the middle line, with its edge directed downwards towards the symphysis and an incision an inch or one and a half inches long is made in this direction Neither a sharp hook nor sutures inserted in the bladder, to hold it up in position, is necessary, but if the patient be stout retractors may be required to separate the edges of the wound in order to bring the bladder into view before incising it.

The knife is now withdrawn and laid aside and as the fluid rushes out the forefinger is introduced into the bladder, plugging the opening If a tumour of considerable size be present it will be felt at once projecting into the fluid in the distended bladder The fluid is allowed to trickle away slowly by the catheter and the finger makes a methodical survey of the bladder, ascertaining the size consistency, position, and mode of attachment of the growth many of which particulars will have previously been recognised by the cystoscope

Removal of the tumour —A suitable tumour forceps (Figs 7, 8, 9, and 10) is now introduced beside the finger, but before doing so the bladder is distended with lotion through the catheter, which should be withdrawn till its end just reaches the inner orifice of the urethra, so as to be out of the way of the forceps Keeping the point of the finger in contact with the tumour, the blades of the forceps are opened and the pedicle of the growth—if it be pedunculated—is grasped as near to the bladder wall as possible and the growth is twisted off. If the tumour be sessile forceps with broad serrated jaws (Fig 7) will be necessary, by which the growth can be grasped flush with the mucous membrane of the bladder and removed partly by biting it away and partly by torsion. If the sessile growth be a large one it will have to be removed piecemeal, the forceps being introduced over and over again, the bladder being kept distended by an assistant throughout the manipulations, otherwise there would be danger of the rugose folds of the bladder getting nipped between the jaws of the forceps and thus injured.

FIG 7

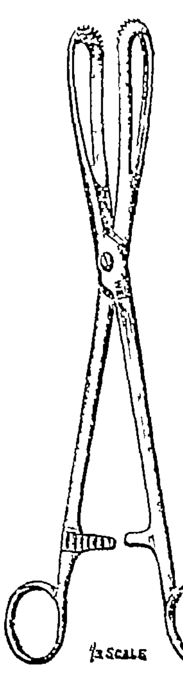


FIG 8

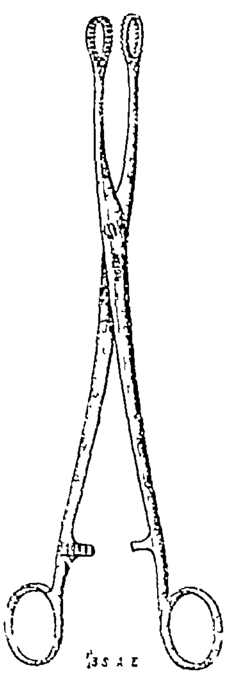

FIG 9

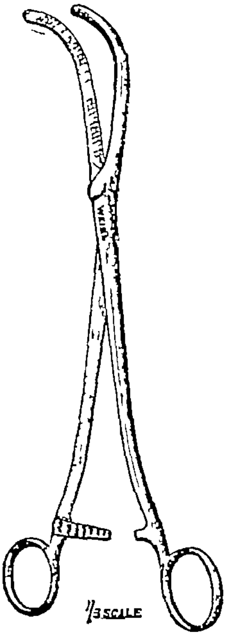

FIG 10

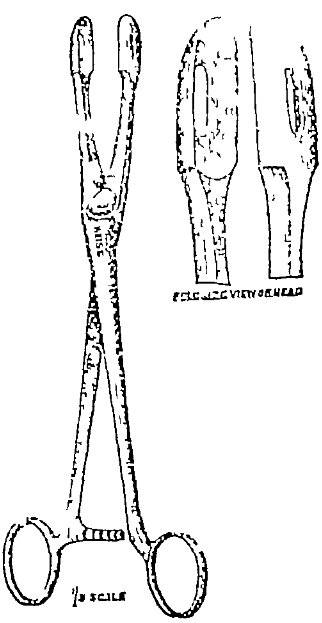

When the tumour has been excised as far as possible in the manner indicated an ordinary glass Fergusson's vaginal speculum is introduced—the largest size that will readily pass through the incision in the bladder being employed—and directed on to the site of attachment of the growth The lotion is allowed to flow away and any remaining fluid is mopped up by sponges introduced on holders through the speculum An electric forehead lamp is employed to illuminate the bladder through the speculum. The distal end of the speculum being pressed firmly against the site of attachment of the growth and the fluid being thoroughly mopped up by sponges, the site of the growth is brought clearly into view by means of the electric forehead lamp Any shreds of growth or nodules left behind will be observed in this manner and can be removed by forceps introduced through the speculum. The electric, or Paquelin's, cautery can also be introduced through the speculum to burn away the roots of the growth or to arrest hæmorrhage. Tincture of perchloride of iron can also be introduced on a sponge for the latter purpose If the growth be sessile and particularly if there be any doubt as to infiltration of the adjacent mucous membrane, the tumour may be grasped boldly by forceps and brought well up into the wound This will be facilitated by an assistant placing his finger in the rectum and pushing the base of the bladder up towards the suprapubic wound. The mucous membrane of the bladder is incised all round the base of the growth but quite clear of it, and this together with the tumour is removed by broad serrated or cutting forceps (Figs. 7 and 10). It is unnecessary and, indeed, inadvisable to attempt to bring the edges of the mucous membrane together over the site of the tumour by sutures It is difficult to introduce sutures at the base of the bladder It is inadvisable to employ other than catgut sutures and they are absorbed too rapidly to be of any practical use, silk sutures should never be used as they form nuclei for the formation of calculi. The tissues are so crushed by the forceps in the removal of the growth that it is doubtful if direct union could take place in any case. Healing of the wound takes place by granulation

The bladder is now thoroughly irrigated by warm boric lotion through the catheter and out by the suprapubic wound till all clots are removed and the fluid flows away clear A drainage tube with two eyes cut in it on opposite sides at distances of about half an inch and one inch respectively from the end is introduced by means of forceps so as to reach the base of the bladder This should be sufficiently thick to fill the wound in the bladder, so that the whole of the urine may flow by this route and thus avoid its trickling beside the tube and entering the prevesical space No object is gained by employing a narrow tube, as in practice it is found that the suprapubic wound heals as rapidly when a large tube is used, and a narrow tube has the disadvantage of allowing the urine to flow beside it, thus infecting the loose areolar tissue in the prevesical space, which in consequence would slough away in gangrenous masses, and of preventing clots from passing out of the bladder

The abdominal wound is now brought together round the tube by means of three or four silkworm gut sutures, which are passed through skin and muscle, and, finally the drainage-tube is fixed in position by means of a superficial suture. Buried sutures should not be employed in suprapubic cystotomy, as they almost invariably get infected by urine and lead to suppuration I never entirely close the bladder wound, invariably introducing a drainage-tube but when for any reason the incision in the bladder is extensive I bring the wound partly together by catgut before introducing the tube. The drainage-tube is cut short half an inch from the superficial wound, cyanised gauze, well wrung out of boric lotion, is applied, and the front and sides of the abdomen are covered by large pads of cotton or wood wool The dressings are changed every three or four hours as they become saturated with urine I have tried appliances of all kinds for conducting the urine directly from the bladder to a receptacle beneath the bed, but have found them one and all unsatisfactory, and I now employ only the simple method above described. The skin sometimes has a tendency to get irritated by the saturated dressings, at the earliest indication of this it should be protected by rubbing in lanolin or oxide of zinc ointment at each dressing after thoroughly washing and drying the surface The drainage-tube is removed in three or four days, when plastic lymph will have been thrown out along its track and the tissues thus protected from infiltration of urine. The bladder should be irrigated through the drainage tube daily or more frequently if the tube gets blocked by clots, by warm boric lotion. After the tube is removed a soft catheter is introduced daily and the bladder is irrigated through this and out by the fistula. The sutures are removed on the seventh or eighth day, but should the temperature rise and the wound appear "angry" one or more sutures should at once be removed to give vent to pent-up fluids in the prevesical space. The fistula takes from a fortnight to a month to close as a rule

When a malignant growth is so extensive that no attempt at its removal is desirable or practicable it may be necessary to open the bladder and to establish permanent drainage for the purpose of ameliorating the terrible pain and strangury that exist, particularly when general infective cystitis sets in and so to allow the patient to pass away in comparative comfort. The perineal or suprapubic route is chosen, according to the nature and position of the growth, so as to afford free drainage and at the same time to avoid pressure of the tube on the growth

Resection of that portion of the bladder wall involved in a malignant growth, and even of the entire viscus, has been undertaken—the ureters in the latter case being implanted in the rectum in the male or in the vagina in the female—hitherto, however, with but poor success. When the growth is confined to the apex of the bladder, where the resection can be performed extra peritoneally by stripping off the peritoneum over an extensive area, I consider that the operation is not only justifiable but advisable. Unfortunately, however, these growths are rarely confined to this region. When involving the base of the bladder I consider any attempt at resection futile, and that if the patient does not succumb immediately to the shock and hæmorrhage attending the operation life is materially shortened thereby

ON REFLEX CONVULSIONS IN GROWING BOYS AND GIRLS

BY EUSTACE SMITH, M D, F R C P LOND,
SENIOR PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN
CONSULTING PHYSICIAN TO THE VICTORIA PARK HOSPITAL
FOR DISEASES OF THE CHEST

THE convulsive attacks so often seen in rickety or highly neurotic infants as a result of teething or other form of flex irritation are familiar to everyone, but it is not so ell known that similar nervous seizures, due also to pure eflex worry *may be found in children* beyond the period of nfancy and even as late as the eleventh or twelfth year he children thus affected are usually *members of families* hich show distinct neurotic tendencies although, perhaps, hey may be free from the graver signs of nervous instability he children themselves are highly strung, excitable and asily moved to tears, but by no means necessarily spiritless r timid. They may have suffered from convulsions during nfancy, but often their special nervous susceptibility is of ater origin and seems to be quite independent of the rickety tate in early childhood.

Occasional convulsive attacks in a child who has passed he period of infancy, and especially in one who is of an age o take regular lessons and to play at boisterous games are ften classed at once as "epileptic and treated accordingly, ut before labeling such a case as one of epilepsy it is wise o consider carefully all the circumstances of the attack with a view to discover some exciting cause to which the eizures may be referred. On inquiry we can often detect remonitory symptoms common to all the attacks and find hat on each occasion the patient for some hours or days efore the seizure had shown very obvious signs of ill health. The seat of trouble is usually the alimentary canal and the irritation appears to be excited by the presence in the stomach and bowels of undigested and fermenting food. The children suffer almost invariably from languid circulation and cold feet. In consequence they have but little resisting power against the evil effects of damp and cold and sudden changes of temperature When exposed to these influences they are liable to contract a more or less severe gastric or gastro-intestinal catarrh and the digestive turmoil thus engendered is often sufficient to throw the unstable nervous system off its balance.

As a rule the nervous attacks are separated by long intervals during which the health, although not, perhaps, quite satisfactory, for the nutrition is rarely good, yet presents no unusual features which seem to call for medical notice. In most cases they are single convulsive seizures which occur once and are not repeated in the same bout of illness, but sometimes they fall into groups or batches, the child having two or three in the 24 hours for several consecutive days. In other cases, again, the convulsive seizures are repeated frequently over a period of weeks. They then cease for a time to return in the same way after a longer or shorter interval In the common case where the fits whenever they occur are preceded or accompanied by gastro intestinal derangement the inference that there must be some connexion between the digestive trouble and the nervous commotion is obvious The isolated attacks are probably purely reflex, as in the case of a teething fit, but when the seizures are repeated frequently day after day for weeks together the mechanism is probably less simple The urine at these times is always very acid and I have thought that the absorption of acid formed in large quantity in the alimentary canal as a result of fermentation of food might tend to keep up the irritation of the nervous system or that the same result might be brought about by microbic infection from the bowel

The special feature of these attacks lies in the fact that they invariably coincide either with a digestive disturbance or with some other form of local irritant and cease at once when the local condition is relieved. To produce its effect the local irritant need not be violent, but if mild its action must be sustained, indeed, the continued working of a mild irritant seems to produce a more striking effect than that of a more powerful stimulus which operates only for a short time. It would appear as if the endurance of the nervous system was gradually weakened more and more until the breaking point was reached and the fit occurred This result is arrived at more quickly when the stimulus acts upon a system already in a state of disquiet. This is well seen in the case of adenoid growths in the naso pharynx. Children who suffer from these vegetations often show symptoms of nervous unrest, and the addition of a post-nasal catarrh may be enough to determine the onset of convulsions The irritation of hard scybalous masses acting upon a mucous membrane already in a state of catarrh may have the same effect, and even the strain upon the eye set up by hypermetropia and astigmatism will sometimes, I have reason to believe, under favourable conditions prove a cause of convulsive fits in neurotic subjects The irritation of worms in the alimentary canal has been often said to be a cause of convulsions, but in my experience this consequence of parasitic irritation is rarely seen The nervous breakdown is said to be more likely to occur in the case of lumbrici than in that of ascarides, but when it is found I am disposed to attribute the commotion less to the creatures themselves than to the gastro-intestinal disturbance which is always associated with them and by means of which they breed and develop *In all these cases* the nervous seizure no doubt is as purely reflex as are the fits which arise from similar causes in susceptible infants, for such disorderly response to reflex stimuli may long outlast the period of babyhood and the rickety state We may find it in schoolboys and schoolgirls and even in young *adults* for there can I think, be little doubt that many of the so-called hysterical' attacks in young unmarried women are of this nature. In the common case where the fits are the outcome of a gastro-intestinal disturbance the account we generally get is that the child every few months has an attack of illness in which he lies about looking dull and listless, is perhaps feverish loses his appetite, and may complain of nausea or try to vomit The bowels are disordered—loose or constipated—and the tongue is thickly furred. In the midst of these signs of digestive derangement the child is suddenly taken with a *mild* fit, he loses consciousness and either twitches or lies with his body stiff in a tonic spasm.

The seizure may be repeated several times. After a few days the indisposition passes off and as the child regains his usual health the irritability of the nervous system also subsides.

In the year 1889 I saw with Dr G J Crawford Thomson a little boy, aged five years I was told that he had had fits ever since his first year and that for the last two years they had recurred every two months or so The mother explained that as a rule the boy's health was fairly good but that for a week before the attack his complexion would turn ash coloured and he would have dark lines under the eyes He would be fretful in the day and restless at night, his bowels would be confined and his feet noticeably cold The fits themselves were immediately preceded by a pain in the epigastrium and a rise of temperature In the fit the boy lay perfectly motionless and quite unconscious. He usually had two or three in succession Before the attacks the stools were clay coloured, afterwards greenish and offensive There was never any vomiting or diarrhœa. In this case the seizures were apparently the result of attacks of gastric catarrh. Treatment was conducted upon this assumption and measures taken to improve the circulation, combined with a careful diet and attention to the digestive organs, soon restored the child to a better state of health. Five years later I heard from Dr Crawford Thomson that the boy was at school doing well and had had no relapse.

A little boy, six years of age, was brought to me in 1889 as he was said to suffer from convulsive fits According to the mother's account the boy had had his first fit at the age of six months, when 12 months old, after an illness which was called "blood poisoning," he had had a second and similar seizure, and since that time the convulsions had been liable to return whenever the child's digestion was upset. At these times he became very irritable and cried a great deal and showed a patch of red on each cheek, his temperature rose, he slept badly, and his bowels were relaxed, then in the course of a day or two he would often become convulsed. In this way he was said to have had quite a dozen convulsive seizures. When in his ordinary health the boy was reported to be bright and active and very intelligent. When I saw him he was bright-looking enough, but his feet were very cold and his flesh was flabby, his colour, however, was good and careful examination could discover no sign of local mischief In this case the attacks of gastro-intestinal derangement were put a stop to by diet and attention to the warmth of the boy's feet, combined with a regular morning douche of 70° F following directly upon a hot sponging The boy was seen 18 months later and there had been no return of the fits although he had had one mild attack of diarrhœa

In the early part of 1901 I saw with Dr E J Moore a boy, aged 10 years, who came of a highly neurotic family and was himself very fanciful and nervous The boy had had adenoid growths removed in 1897 At that time he had been very anæmic and was subject to attacks of gastric catarrh, but by management and careful diet he had overcome this tendency in a great measure and was getting stronger and gaining colour In February, 1901, the boy was much worried by a tender tooth and a few nights later, after a visit to a theatre, was taken in his sleep with a convulsive fit. For some weeks afterwards he remained in a highly nervous state suffering greatly from night terrors In October of the same year he woke up suddenly one morning at 6 A M gasping for breath and fell into a fit in which he foamed at the mouth and was quite unconscious. The previous afternoon he had played football for two hours at his school and had seemed perfectly well on going to bed In April, 1902, he had another fit which occurred like the last in the early morning and roused him from his sleep His digestion at this time was disturbed for he complained of nausea soon after the fit and said that "his inside felt all bubbling up" He continued to suffer from bad dreams and would often wake up at night crying out that he was choking I examined this boy carefully on several occasions with Dr Moore, but beyond a certain amount of indigestion and a tendency to constipation could find nothing amiss. Something, however, led us to suspect that he was straining his eyes, and this suspicion was confirmed by Mr Ernest Clarke who ordered the patient glasses for hypermetropia and astigmatism The boy began to use the spectacles in April, 1902, soon after the last fit. From that time he improved greatly in health and became, as they said, "a different boy" Nine months afterwards he was reported to be lively and merry, absolutely free from all terrors or nervous apprehensions, and sleeping soundly all the night through.

I cannot help thinking that in this case the relief from the strain upon the eyes is answerable in great measure for the improvement which happily occurred, and the boy's mother who watched him with the utmost care is convinced that it is so The boy was evidently living in a state of extreme unrest and I could find nothing else to account for the flustered state of his nerves. It is, of course, too early as yet to say that the tendency to convulsive attacks has been overcome, but the improvement in the general health is so marked and the boy's nervous excitement has so completely disappeared that I shall be surprised if the seizures return. The boy was always bright and intellectually active and never had difficulty with his lessons He had had no fits in infancy At the time that the glasses were ordered he began to take a dose of strychnia solution (two minims) and liquid extract of ergot (20 minims) three times a day but the improvement was in my opinion too rapid to be attributed to the drugs

A little boy, aged four years and eight months, was sent to me by Dr Robert Allan. There was a neurotic family history on one side but the boy had not shown any definite sign of nervous disorder until March 5th 1900, when without any warning he suddenly fell off his chair in a fit Since that time the seizures had been repeated frequently The attacks were of two kinds. He had regular fits in which the whole body was convulsed on both sides These were of varying severity and occurred not only in the day but also at night and often took him in his sleep. As a rule he lost consciousness, but in the milder attacks he was sometimes thought to be conscious although his eyes had a fixed stare. The regular fits were mixed with others which were mere occasional and transient muscular contractions. They called these "jerks" In them a spoon or other object would be tossed suddenly from his hand, or his legs would give way beneath him and he would fall to the ground, but would rise again at once without any difficulty When the boy was nervous or excited the "jerks" were almost incessant. They generally occurred every day, sometimes only once or twice, but often more frequently One peculiarity of the case was that the attacks, both fits and "jerks," occurred in batches—so many days affected, so many free. Thus, no "jerks" occurred between the end of March and June, 1900, he then had them almost constantly for four days. Afterwards he was free again until September when he suffered in the same way for ten days. During all this time the severer attacks were occurring at intervals. Since October, 1900, all the attacks, both fits and "jerks," had occurred in groups, being present for two or three weeks and then absent for about the same period. When free during this time he had been free both from fits and "jerks."

I saw the boy for the first time on April 23rd, 1901. He was in fair condition with a good colour and his heart, lungs, and other organs were healthy He suffered greatly from constipation and his stools consisted of very hard lumps covered with stringy mucus They were evacuated with great difficulty and much jerking of muscles This condition of the bowels had dated from the time of the first fit, since which event he was said never to have had a natural stool although before the fit the bowels had always been perfectly normal. Not long before his visit to me the boy had passed a quantity of lumbrici and ascarides but without any relief to his symptoms He had never complained of abdominal pains or other kind of discomfort but since his illness, although perfectly intelligent and rational, he had from a cheerful, contented boy become peevish and irritable in his temper and very difficult to please. His feet were very cold and his circulation was said to be habitually languid As the boy lay on the couch while I examined his abdomen he had frequent little jerks of his head towards the right side and slight twitching movements of his right hand Now and again he would have a stronger jerk and occasionally he heaved a deep sigh. His pupils were normal and there was no nystagmus. The jerking movements were not at all like the irregular muscular contractions of chorea. As a rule they were isolated jerks and occurred only once or twice in the day or were even absent altogether for weeks at a time. It was only when the boy was at his worst, especially when nervous or excited, that the movements were repeated with any frequency Sometimes, however they were almost continuous and then his articulation would be difficult. The boy had already been put upon a diet in which acids and acid making foods were carefully restricted in amount and he was taking bromide with an occasional aperient.

In suggesting a remedy for this state of things I cannot say that I felt very hopeful of success, especially as the boy had been treated with so much judgment from the very beginning It appeared to me, however, that the profuse mucous secretion from the bowels denoted a high degree of intestinal irritability and that the passage along it of hard scybalous masses could not but be a source of extreme irritation. I therefore advised that we should try to improve the circulation by a course of morning douches of the temperature of 75° *F* given immediately after a hot bath, for if by this means we could reduce the boy's susceptibility to chills there would be a prospect of curing the intestinal catarrh and removing the worry from the bowels by a rigid diet and a succession of mild aperients *For medicine* I suggested giving the liquid extract of ergot (20 minims) with liquor strychniæ (one minim) three times a day after food. I regard this combination as one of singular value in all forms of nervous irritability in the child. The bowels were to be kept regular by a nightly dose of liquorice powder This treatment was carried out perseveringly by Dr Allan The boy got a good reaction after his douche and his feet became warmer Very soon he began to put on flesh and his nervous symptoms diminished The fits and 'jerks" still recurred at intervals but in a less severe form and the boy's spirits became brighter and his temper more placid. On Dec. 30th, 1901, Dr Allan reported 'The boy has had no regular convulsion since July and no 'jerks' since September, he has gained weight and is happy and cheerful instead of irritable and cross The bowels are kept regular by mild doses of liquorice *powder, but still a little mucus* passes occasionally" The last report, in December, 1902, stated that no further fits or "jerks" had been noticed that mucus had ceased to appear in the stools, and that the boy attended school regularly and seemed to have completely regained his *former good health*

In this case the results of treatment seem to leave little doubt that the nervous derangement was the direct result of intestinal worry As the bowels had been perfectly normal up to the time of the first fit, but never afterwards, it seems probable that at that date the boy had suffered from an attack of acute gastric catarrh. This derangement is not only a common cause of convulsive seizures in neurotic subjects but is apt to leave behind it a susceptibility to chills which, if disregarded, may be a fruitful source of mischief In consequence of this susceptibility the boy *seems to have suffered* from repeated attacks of mild catarrh of the colon which led to a continuous over secretion of mucus ('mucous disease") and started the constipation which was the cause of so much of his trouble. The happy result I attribute entirely to the energetic and painstaking way in which the treatment was carried out by Dr Allan. The *gradual weakening* and final stoppage of the fits and the return of the boy's normal placidity of disposition seemed to go hand in hand with the reduction of the catarrh and the improvement in the state of the bowels, and when the mucous discharge ceased to be *noticed* the nervous irritability also came to an end. Whether the ergot and strychnia had any part in the improvement I cannot say, but it is likely that the sedative and tonic effect of these remedies helped the nervous system to recover its tone directly the primary irritation had been put a stop to

I might bring forward more instances to illustrate the subject of this paper, but the above are sufficient examples of a condition which is far from being an uncommon one. If a child whether he be or not of known neurotic tendencies, begins to suffer from periodical fits we must not too hastily assume that the case is a serious one or *that the* patient is, or is likely to become, epileptic. If we are able to connect the seizures with a local irritant or passing derangement of organs we have reason to hope, and even to anticipate, that the removal of the disturbing influence may restore quiet to the nervous system. *Our* treatment should be directed to this end and instead of flying at once to bromides and other nervine sedatives we should search without delay for the exciting cause and adopt prompt measures for its removal

I desire to insist upon the fact that it is not only in children who suffer from some obvious and *definite local* worry that reflex convulsions are observed, indeed, if such a condition be present it is not necessarily the cause of the attacks. Thus, in the case last recorded, the boy passed some long worms and a quantity of thread worms, but nevertheless the turmoil of the nervous system was in no way allayed by their expulsion. It is evident from the cases narrated that where the nervous system is impressionable and unstable a moderate irritation, *if long sustained*, may keep the system in a state of continual unrest so that any further provocation even a very slight one, may increase the irritation to an unbearable degree.

It will be noticed that in the instances quoted above there is one common symptom upon which some stress has been laid—viz, that the feet have been habitually cold ' The symptom is one to which little importance is usually attached but it betokens a condition which, if disregarded, may thwart our best efforts to treat with success the more chronic complaints of childhood. With cold feet a child's susceptibility to chills is so heightened that he can no longer offer an effectual *resistance to sudden changes of temperature*, and a chill in a young subject in whom the metabolic processes are maintained at high pressure in order to respond to the urgent demands of growth and development almost always means a digestive upset Nutrition suffers at once and any weakness or injurious tendency is aggravated. That the nervous system *should* be *thrown so readily off its balance* argues, no doubt, a high degree of nerve instability, but this is far removed from the epileptic state and need not necessarily be permanent. If such impressibility can subside under favourable conditions in an infant it seems not unreasonable to hope for equally good results in an older child. As a rule, indeed, *nervous seizures of this character* are as harmless to the older children as they are to the infant, the storm passes off and leaves the patient no worse than before. *It may happen, it is true, that attacks* which are apparently of this nature persist and become a permanent source of weakness. Thus I have known the seizures to continue to recur in spite of treatment, each time with less and less provocation, until at last they arose apparently spontaneously without any detectable exciting cause. But even *in these cases, as far as I* have been able to follow them out, the general health seems to suffer little if at all from the attacks, the intellect remains unaffected and the child, if a boy, can go to school and hold his own with his fellows It is *probable that these cases* are not true cases of reflex convulsions even at the beginning, but as long as they remain *definite convulsive seizures coming* on only when the health of the patient is disturbed I do not know how they are to be distinguished. The main *point is* that such cases are really exceptional In the large majority of instances where the fit occurs in a child who is the *subject* of a temporary digestive upset we may reasonably expect that by judicious treatment the seizures may be put a complete stop to and the patient's health permanently restored. Many observed cases warrant me in saying that young persons who have been subject to such seizures to a period as late as 12 years old may grow up into perfectly healthy adults without showing any sign of having suffered in mind or body from a weakness which has long become a thing of the past

Queen Anne-street, W

THE PREVENTION OF SEA-BORNE PLAGUE

BY RICHARD FREER, M.A., M D CANTAB,
LATE SURGEON PENINSULAR AND ORIENTAL STEAM NAVIGATION COMPANY

I HAVE recently spent 12 months as surgeon on steamers trading mainly with Bombay and the Far East *During* that period I took the opportunity of making observations, as occasion offered, on the methods adopted to prevent the spread of plague and on the manner in which they were carried out I hope this account may prove of use to those who, while taking an interest in the subject, have not had the opportunity of becoming personally acquainted with the routine employed and whose knowledge of the subject is mainly derived from Blue-books and Parliamentary reports

By the Venice Convention certain regulations were recommended to be carried out by the sanitary authorities of ports infected with plague, these regulations especially applying to Bombay These consisted mainly of the examination of the crew and passengers on shore and the disinfection of the clothes, effects, and bedding of natives on shore.

At Bombay the following methods are adopted At an early hour on the morning of leaving the port the native crew are assembled with their belongings in a large building about a quarter of a mile from the docks. There they strip and the clothes they were wearing, together with their bedding, &c., are sterilised by steam. Their shoes are sprayed with a solution of perchloride of mercury and the boxes in which they keep their belongings are scrubbed by themselves at water taps provided for the purpose. They then take their boxes to a native who sprays the interior with a very small quantity of some disinfecting solution The men in the meanwhile have arrayed themselves in clean clothes which are not disinfected.

The disinfection of the clothes was very inadequately carried out on the two occasions when I witnessed it. The clothes came out of the steriliser like boiled puddings, wet and sodden I mentioned this to one of the port medical officers who explained that the fault did not lie with the machines used, but that they were worked by natives who could not be relied upon to get up a sufficient pressure of steam—a result which was due to an ill advised economy often met with in the East. The disinfection of the shoes was very superficial. The average native shoe or slipper is a dirty object, especially that of the fireman and coal trimmer It is full of nooks and crannies in which any germ would flourish exceedingly, being made of soft leather and usually embroidered A mere spraying with any disinfectant, however strong, could not possibly sterilise the whole of the shoe. The scrubbing of the boxes and subsequent spraying is a most farcical proceeding The man holds his box under the tap, gives it half a dozen scrubs on the top and as many on the bottom, holds it open before the spraying machine for a few seconds, and then trots off to the steriliser for his clothes The native also brings in his box household goods in variety—tins, wooden boxes, looking-glasses, and pots of grease, besides many others of an unknown nature. These are laid out for inspection but are not disinfected, though why they should be considered less likely to be infected than the clothes it would be hard to say The crew are then examined in a shed in the docks, and this examination, as a rule, is thorough. The primary object is to detect rise of temperature and enlarged glands And here I may enter a protest against the method of detecting the latter by means of a sharp prod in the groin and armpit. This is a most dangerous procedure for obvious reasons and if the person examined were of a stoical nature it would reveal nothing

Rats are well known as disseminators of plague. I have personal knowledge of one ship on which dead rats were found lying about some days before an outbreak of plague took place. It is therefore very important to prevent rats from boarding a ship in an infected port. This is, of course, recognised at Bombay but the means employed are very ineffective. Funnels are provided which are attached to the ship's cables with the large aperture downwards To these, as at present employed, there is the objection that rats will jump from the cable to the edge of the funnel and so get on board ship—this I have learnt from several credible eye-witnesses. Three or four lengths of wire rope are generally used to moor a large sized vessel and the funnels cannot possibly be fastened on all of them as the different lengths of rope lie too close together The usual plan is to place the funnel on any length of cable which lies far enough from its fellows to allow the funnel to fit in between, letting the other lengths take their luck. Manila cables are frequently used. These are large ropes three or four inches in diameter, much too big to allow the funnels provided to be placed on them, although they offer a most obvious and safe pathway for rats. Rats will frequently come up the gangway ladder and nothing is done to hinder them. Lighters, native boats, &c , are fastened alongside often in great numbers , some of these must harbour rats yet nothing is done to prevent them from coming on board. When a ship is loading at an infected port the object should be to prevent rats from coming on the ship When the same ship reaches a healthy port the rats should, as far as possible, be prevented from leaving the ship I have never seen the funnels reversed—they are always placed with a view to prevent the rats from coming on board. This I have seen in a ship lying in the port of London and newly arrived from Bombay The use of funnels at Bombay appears to be entirely optional, as I saw a good many ships lying in the port without them. And when they are used it seems to be considered sufficient to place them anyhow on the rope I have seen funnels so attached to the cables that a large hole was left in the mouth of each one, this being due to the careless way in which they were put on. It is impossible in some circumstances, such as the relative size of the cable and the funnel, to avoid leaving a hole in the funnel , and these holes are nearly always plugged loosely with tow or cotton waste instead of with a wooden plug cut to fit. The funnels are generally placed on the sag of the rope, so that the edge of the funnel is tilted towards the rope and often nearly touches it

The killing of rats on board ship is a very necessary procedure when the presence of infected rats on board is known and also as a preventive measure It is, however, a very difficult thing to do thoroughly, especially in passenger steamers which carry a large amount of perishable stores and are fitted with all kinds of wooden partitions Sulphurous acid has been tried and in one instance, to my knowledge, with very partial success It has many disadvantages and can only be used if all the stores and a considerable amount of woodwork be removed, and it will not kill the rats unless it is very condensed Carbonic acid gas will kill rats if it reaches them, but it is very heavy and non diffusible and rats might be able to climb to the upper parts of the ship out of the way I once tried driving rats out of a hold with the fumes of burnt red pepper I very much doubt if there were any rats—at any rate none appeared—though the effect of the fumes on the sportsmen who were waiting to kill the rats as they came up on deck was heartrending

A memorandum on the influence of rats in the dissemination of plague, by Dr W J Simpson, was issued from the colonial secretary's office at Hong Kong in 1900 Dr Simpson especially emphasises the fact that plague attacks rats before human beings, and after dealing with the destruction of rats on shore he makes the following suggestions for killing them on board ship He states that "the destruction of rats on board ship is peculiarly difficult" and "no method hitherto devised has proved entirely satisfactory" He recommends sulphurous acid, carbonic acid gas, and a substance called "pictoline." The methods which he advises for their use could only be employed on cargo steamers He is apparently under the impression that cargo steamers necessarily harbour more rats than do passenger steamers This, as a rule, is not the case. In a cargo steamer the whole of the space beneath the main deck is devoted to holds, with the exception of engine-rooms and coal bunkers, and these holds being made of iron throughout do not provide a comfortable home for rats. On the other hand, passenger steamers are honeycombed with wooden partitions and carry a large amount of edible stores. I once saw the hold of a large cargo steamer emptied and not a rat was to be seen, although search was made for them. In the same steamer 30 or 40 rats were trapped on the voyage in the storeroom and in the crew's quarters Of course, grain ships and others the cargo of which mainly consists of foodstuffs might harbour a very large number of rats, but ships coming from the East mostly carry cargoes of non-edible material

With regard to the detection of plague on board ship at ports of call I can only give the routine employed on ships which carry a surgeon. At Colombo, Penang, and Singapore the mean temperature is too high for plague to flourish and no especial precautions are adopted, though ships sailing direct from Bombay to Colombo are there placed in a modified form of quarantine. At Hong Kong the surgeon's certificate of good health suffices but if there are any suspicious cases on board the port surgeon examines the crew At Shanghai there is a regular inspection of the ship's crew and passengers and the native crew are thoroughly examined There are very complete arrangements at this port for quarantine, &c. In Japan the ship is boarded by four or five gold laced officials who make from a Western point of view, a very curious examination of the ship's crew Among other solecisms, to feel the pulse with the ball of the thumb or palm of the hand is quite usual. At Suez the native crew is examined and the passengers and white crew are inspected, a lady doctor being available if her services are required, and at Marseilles the same routine is practised.

Owing to the precautions taken it is most unlikely that any person infected with plague can board a ship at an infected port. Therefore the large majority of such cases of plague as are found on ships from time to time are, in all probability, infected on board, either by rats clothing, bedding, or cargo, and seeing that cases of plague on board ship still occur far more frequently than they should do I think that the time has come for the recommendations of the Venice Convention to be reviewed and modified. I am strongly of opinion that no native sailor should be allowed to bring any clothing or effects from his home on board ship, even if disinfected. This may appear to be a drastic measure but it is not so in reality and would probably cost less than the present cumbrous mode of disinfection. It would be no difficult matter for the port authorities to establish a depôt where the native sailor could deposit all the clothes and belongings necessary for his sea life during the interval between his discharge from one ship and his engagement on another These could be disinfected if considered necessary This would at least minimise the chances of clothes being brought in contact with plague

The question of rats is a more difficult matter to deal with The funnel when modified seems to be the best method of preventing rats from climbing cables. Each funnel should have *chevaux de frise* of sharp-pointed wire round the circumference, to be coated with some substance obnoxious to rats. These should not be of one stereotyped pattern, but they should be made in such shapes as circumstances may require, and the shapes necessary can only be found out by experience. They should be fixed by the shore authorities and if natives are employed they should be under the direct supervision of a European, and, lastly, the funnels should be placed on the most perpendicular part of the rope, that is, as near the hawse-hole as possible. I do not think it possible to kill all the rats on board any ship by any means short of sinking But I do think that a thoroughly organised system of catching rats by traps or other means would reduce their number to a minimum. It is well known that rats resort to the ship s boats for water and of this fact advantage should be taken. Any live rats seen on board, as well as the daily tale of those killed, should be noted in the log book, and it should be considered as important to keep the number of rats down on board ship as to keep the brasswork clean.

There is one more subject I should like to call attention to Each port makes its own regulations for granting *pratique* to vessels entering it. The result of this is that there is no continuity of action and that while one port may take every precaution to safeguard itself it may nevertheless make no provision to prevent infectious disease from being carried through to another port. The following is an instance. Two cases of illness broke out on a steamer sailing from Bombay on the day before arriving at Colombo These cases were carried through Colombo Penang and Singapore to Hong-Kong, where they were discovered to be plague In the meanwhile infection had spread to two other persons How many more were infected I do not know, as I left the port on the day all this was discovered. Now, if each port were treated not as a unit but as part of a continuous system this probably would not have occurred, as every case of illness would be examined with a view to future contingencies and any case not above suspicion would be removed from the ship This is a matter of considerable importance and directly affects the health of the whole world. It should surely be administered by the central government of the country and not left in the hands of local authorities A scheme should be devised by an international commission of all civilised nations that would be fundamentally the same for all ports differing only in such details as may be found necessary to deal with special epidemics It would be outside the scope of this paper to enlarge on this subject, but its importance and the self evident deficiencies of the system employed must form my apology for mentioning it.

Rugeley

FATALITIES TO WORKMEN CAUSED BY BREATHING SULPHURETTED HYDROGEN

BY THOMAS OLIVER, M.A. DURH M D GLASG,
F R C P LOND
PHYSICIAN TO THE ROYAL INFIRMARY NEWCASTLE UPON TYNE.

AT a graving dock in course of construction at Hebburn-on Tyne there occurred on July 17th, 1902, a serious disaster whereby three men were suddenly deprived of life. A similar accident took place on August 25th. On this occasion one man was killed and three men just escaped losing their lives. In the process of excavation the contractors had found it necessary to use a large iron cylinder or caisson. The cylinder at the date of the first accident was 48 feet deep and nine feet in diameter, 15 feet of the caisson projected above the level of the dock. In excavating the 33 feet of soil the workmen in the cylinder passed through sandy clay, stiff clay, gravel, and in the month of July they had reached the boulder clay From the amount of slag that is lying upon the ground the site of the proposed dock must have been occupied many years ago by iron furnaces, while close to where the iron cylinder has been sunk there is a large heap of refuse and tank-waste deposited there half a century ago from chemical works that have long since disappeared. This alkali waste lies on the clay close to where the excavation is being made by the men in the caisson and from it there is a certain amount of drainage. The refuse from chemical works is a nuisance to a neighbourhood in more ways than one. When rain falls upon the waste sulphuretted hydrogen is given off which impregnates the atmosphere, while the liquid that drains away contains sulphur compounds that destroy vegetation. Although the alkali waste had not previously caused alarm at the Hebburn dock so far as the evolution of gas is concerned, it was yet the source of disagreeable sulphurous odours. On the occasion of my visit to the excavations three days after the disaster in July the odour of sulphuretted hydrogen in and close to the place where the caisson is sunk was extremely pungent. The lower part of the cylinder reeked with it. The story of the fatal accidents is briefly this.

At 6.30 on the evening of July 17th a workman entered the cylinder He had been inside about 20 minutes when screams were heard. A comrade, believing that his mate had been overcome by gas, descended the caisson to render assistance, but in a very few minutes he too shouted and fell to the bottom, having been overpowered by the fumes. A third man went at once into the cylinder to give help, but he too was immediately poisoned. Within the incredibly short period of a few minutes three men were lying lifeless at the bottom of the caisson in three inches of water from which strong fumes of sulphuretted hydrogen were being evolved. The works manager allowed himself to be tied to the chain of a crane and lowered into the cylinder but he was overcome by the gas and had to be withdrawn. He, however renewed the attempt and succeeded in getting hold of one of the men with grappling irons, but in hoisting the body the belt broke. Subsequently a diver went into the caisson, but he also failed to recover the bodies. A gang of three workmen thereafter tried to reach their fallen comrades, but on account of the fumes they were obliged to desist at a point 15 feet from the bottom of the cylinder It was not until next morning that the bodies were recovered As naked lights burned well in the caisson on the night of the accident it is apparent that the poisonous gas was not carbonic dioxide nor was it gas of an explosive nature. Assisted by Mr. Malcolm of Hebburn, who had been called to the dock after the occurrence of the accident I made a limited post mortem examination on the bodies of two of the men three days after death The first was aged 23 years He had a well-developed and muscular body, rigor mortis was passing off. The right ear had been torn in removing the body from the caisson and dark blood had kept dripping from the wound ever since. The face was pale and slightly cyanosed. Owing to the opacity of the cornea it was difficult to determine the state of the pupils. The body was not decomposing rapidly On opening the cavities no odour of sulphuretted hydrogen was detected The heart was normal in size—the right side was extremely flaccid and empty, the left was hard, contracted, and empty The lungs were slightly œdematous and pale. The liver was dark. The abdominal viscera were healthy The blood was dark and fluid, some of this was removed from the vena cava for spectroscopic examination. The second man, whose age was 19 years, had a well developed and muscular body, rigor mortis was still present, his hands were tightly clenched as if death had taken place in a convulsion His face was cyanosed, so too were the neck and upper part of the chest, while the hands and arms were extremely pale. No odour of sulphuretted hydrogen was obtained on opening the large cavities of the body As regards the heart a small quantity of serous fluid was present in the pericardial sac, the right heart was flaccid and empty, the left was firmly contracted, hard, and empty The lungs were pale and œdematous The liver was dark. The abdominal viscera were healthy The blood was dark and liquid. Some of this was removed for spectroscopic examination. The veins, generally speaking, contained very little blood.

The blood gave the spectrum of oxyhæmoglobin. There were two distinct bands between the yellow and the green The hæmoglobin was easily reduced by means of ammonium sulphide. There was therefore no carboxyhæmoglobin present in the blood, so that the gas which killed the men was clearly not carbon monoxide The spectroscope gave no further information

As the air in the caisson was redolent of sulphuretted hydrogen it seemed probable that it was this gas that had poisoned the workmen Accordingly, through Mr H J Wilson, His Majesty's Inspector of Factories, I received a sample of the water taken from the bottom of the cylinder This I submitted to Professor Bedson of the Durham College of Science for chemical analysis The following is his report "Evidently a brackish water containing a little iron sulphide in suspension, also some sulphuretted hydrogen dissolved in it The results of examination are as follows Specific gravity, 1 011, total solids, 984 grains per gallon The solids contain the following radicles sodium, potassium, calcium, magnesium and iron, chloride, sulphate and sulphide. The water on boiling gives off sulphuretted hydrogen, 100 volumes of water gave 12 2 volumes of this gas This estimate may be considered low, as on standing some of the gas is decomposed, and as I was unable to make the examination on the day I received the sample there may have been a loss on this account"

For some time after the accident just recorded the men refused to enter the cylinder, but by degrees their repugnance was overcome and the work of excavation again proceeded apace. On August 25th another disaster occurred whereby one man lost his life in the caisson and three others just escaped. By this date the cylinder, now lengthened, had sunk further into the ground The boulder clay had been penetrated and sand had been reached There were 46 feet of water in the cylinder About the level of the water, or about 15 feet from the upper end of the caisson, there was a wooden platform. On August 25th a diver had been working at the bottom of the caisson and after having been thus engaged for an hour he came up to the platform where a workman, aged 28 years, in attempting to remove a glass window from the front of the diver's mask was immediately overcome by gas and fell into the water almost on to the diver The diver shouted for help and for air, which had been stopped, to be again pumped to him. A workman who went into the caisson to the rescue was immediately overcome by the fumes, as also was a youth who tried to render assistance There were now four men in the caisson, all of them more or less overpowered by the fumes, for although the diver was receiving air he experienced the sensation as if he was whirling round and round, and but for timely assistance he too would probably soon have become unconscious Mr A M G Walker of Hebburn was on the spot when the men were removed from the caisson. Three of the men were more or less ill, one of them being completely unconscious, while the man who had removed the glass from the diver's mask was found to be dead, his face being dark as if he had been suffocated Attempts were made for a lengthened period in his case to restore animation, but unsuccessfully By means of strychnine and ether administered hypodermically, artificial respiration, plenty of fresh air, occasional inhalations of oxygen, warmth externally, and stimulants, Mr Walker succeeded in restoring the three men, one of whom stated afterwards at the coroner's inquest that in about a minute and a half after entering the caisson he had become unconscious and therefore remembered nothing more.

In the hope of throwing light upon the dangers incidental to breathing sulphuretted hydrogen I exposed a healthy dog weighing 12 pounds 9 ounces to the influence of the gas prepared and administered by my colleague Dr R. A. Bolam, to whom I acknowledge my indebtedness for his assistance in the experiment. Respiration of an atmosphere containing 0 02 per cent. of sulphuretted hydrogen produced no effect upon the animal nor did inhalation of air containing 0 045 and 0 075 per cent. of the gas. When the dog was placed in an atmosphere containing 0 15 per cent. of sulphuretted hydrogen it very shortly afterwards and without any sign of distress or warning, suddenly became rigid and fell apparently dead, the breathing being the first to cease. Occasionally, and at long intervals, a feeble beat of the heart could be heard Artificial respiration soon restored the animal. In two and a half minutes the dog was quite itself again and was allowed to move about freely for some time. On the animal respiring air containing 0 15 per cent of sulphuretted hydrogen, apparent death occurred in 1 minute 40 seconds, being preceded by strong muscular spasm and stoppage of breathing The heart continued to beat for a period On exposure to fresh air the animal soon revived In repeating the experiment the same events took place There might be one or two deep gasping inspirations, or without these the animal would suddenly fall apparently dead in a state of extreme rigidity and with its breathing entirely suspended. Occasionally very marked fibrillary tremor could be observed over the whole body and in this condition of suspended respiration, while the heart could be felt beating very quickly, feebly, and irregularly the animal could be resuscitated by artificial respiration With each re-exposure to the sulphuretted hydrogen, but never exceeding 0 2 per cent., the dog was more quickly and more profoundly affected. It took the animal longer time to recover, it seemed to be suffering from shock as well. The respiratory mechanism appeared to be totally deranged, the automatism of the respiratory centre was so disturbed that it was with difficulty and only after a lengthened exposure to fresh air that the breathing again became rhythmic When respiration was re-established it was quick, 40 to the minute, the beat of the heart was quick and irregular The pupils were dilated When the animal had recovered from a deep administration it was evident that the gas had profoundly affected its nervo-muscular apparatus, for it could not stand unaided and its limbs remained in a state of rigidity There is not the least doubt that sulphuretted hydrogen causes death, and that very rapidly too, by its effect upon the respiratory centre. Death is sudden and apparently painless The animal simply falls down dead without warning This may be preceded by strong muscular rigidity with slight convulsive tremor accompanied by one or two deep gasping inspirations, and although the breathing is suspended for a period the heart may yet continue to beat quickly, feebly, and irregularly At this stage recovery is possible. On examining the body of the dog after death the heart was found to be flaccid, dilated, and filled with dark fluid blood on both sides From the right auricle blood was removed for spectroscopic examination The lungs were pale and presented nothing abnormal Through the spectroscope the blood showed the two bands of oxyhæmoglobin and was found to be readily reduced by means of ammonium sulphide

So far as concerns the data furnished by the necropsies on the bodies of the two men and dog just alluded to there was nothing detected at the post-mortem examination that can be said to point conclusively to death having been caused by inhalation of sulphuretted hydrogen The diagnosis rests largely upon the character of the surroundings and the mode in which death was induced. In looking over the literature of the subject I find that in nearly all the cases, with one or two exceptions, where death took place rapidly no pronounced pathological lesions have been found and no definite spectrum has been given by the blood.

In order to ascertain whether blood in contact with sulphuretted hydrogen would show a particular spectrum diluted defibrinated blood was exposed to the gas by Dr Bolam and myself We made three experiments. 1 H S was passed through defibrinated ox blood for *one minute* The liquid became chocolate coloured and then slightly green. On examination it gave the spectrum of methæmoglobin—viz., one band in the red and two in the green On adding ammonium sulphide and heating the liquid no reduction at first took place, but after standing for some minutes the fluid assumed a greener colour and by degrees reduction was effected 2 In order to determine what degree of exposure to the gas was necessary for the blood to give the spectrum of methæmoglobin sulphuretted hydrogen was passed for *20 seconds* through diluted defibrinated blood Examined immediately afterwards the two bands of oxyhæmoglobin were found to be still present. By degrees the liquid on standing became dichroic, appearing green by reflected and red by transmitted light, it now gave the spectrum of methæmoglobin, the liquid meanwhile becoming darker and greener to the naked eye. 3 In another experiment sulphuretted hydrogen was passed for only *five seconds* The appearance of the blood at first was unaltered and the spectrum was simply that of oxyhæmoglobin. On examining this blood spectroscopically every minute we found that it was not until four minutes had elapsed from the time of removing it from contact with gas that there began to appear a line in the red of the trum indicating the presence of methæmoglobin. The d itself by this time had become slightly like prune-juice olour. In another minute—i.e., five minutes after sul- retted hydrogen ceased to be passed through the blood— spectrum of methæmoglobin was distinct. Where sul- retted hydrogen acts upon blood for only a very short e methæmoglobin is apparently not immediately formed. s probable, therefore, in fatal cases of poisoning that man ot exposed long enough to the gas for methæmoglobin to elop for as we have seen it was not present in the fatal es alluded to above.

n addition to being evolved from alkali waste sulphuretted rogen is found in drains and cesspools and is due to omposing matter. Other gaseous products of putre- tion such as carbonic acid, carbon monoxide, and monia are also usually present. The effect of breath such foul air will be largely influenced by the es other than sulphuretted hydrogen, that are present l their amount. Usually there is a deficiency of gen. As far back as 1884 Grehant and Peyron nonstrated the point at which sulphuretted hydrogen ked with air became poisonous. In order to kill a dog yron found it necessary to employ a mixture of 1 in 500 ere is not the least doubt that the injurious effects of phuretted hydrogen are not sufficiently appreciated by mbers of the medical profession who have not made emselves acquainted with the literature of the subject or testing its action. Dupuytren and Thenard found air ntaining 0·66 of this gas per 1000 poisonous for birds, 25 per 1000 poisonous for dogs, and 4 per 1000 poisonous horses. Lehmann observed that air containing 0·13 of e gas per 1000 caused local signs of irritation, the effect ing probably a narcotic one judging from the position sumed by the animals experimented upon. When men rking in sewers are obliged to breathe an atmosphere ntaining a fairly large amount of sulphuretted hydrogen ath is often instantaneous, and at the necropsy, as in y own cases, no constant pathological changes are found the body unless it be slight œdema of the lungs and the ct of the blood being dark and fluid. The chambers of the eart may contain fluid blood, but this is not always the case, s in two of the three men killed in the accident in July at ebburn the heart was empty. Lehmann,[1] in addition to is experimental work upon the effects of sulphuretted ydrogen, records the case of three men who breathed an mosphere containing 0·2 of the gas per 1000 of air. Within om five to eight minutes there was intense irritation of the yes, nose, and throat and after 30 minutes they were unable remain in the atmosphere any longer. Air containing 5 of sulphuretted hydrogen per 1000 is according to him, e utmost that can be breathed with safety. Even in this uantity (0·5) it caused in less than half an hour smarting f the eyes nasal catarrh, dyspnœa, cough, palpitation, reat muscular weakness, headache, and faintness, with cold weats. According to Lehmann an atmosphere containing om 0·7 to 0·8 of sulphuretted hydrogen per 1000 of air is angerous to human life and from 1 to 1·5 per 1000 destroys fe rapidly, the symptoms even coming on after withdrawal rom the poisonous atmosphere. There must be, however an liosyncrasy to the effects of this gas if the statements f some writers are to be regarded as trustworthy. In he Encyclopédie d'Hygiène et de Médecine Publique," ibre VI., Layet deals with this subject and mentions the act that some men can bear the absorption of relatively arge quantities of this gas without experiencing any incon- enience. Parent-Duchatalet respired for some time an tmosphere containing 29 per 1000 without suffering any ll effects. My own opinion is that sulphuretted hydrogen is an extremely poisonous gas and in this I am supported by nost writers. Haldane[2] says in writing of white damp, hat the poisonous constituent of this gas is CO, occa- sionally, however, H_2S is also present in formidable proportions. The latter gas is extremely poisonous, as little as 0·07 per cent. being capable of causing death if breathed for a length of time. Air containing 0·2 per cent. kills warm blooded animals within one and a half minutes. A. P. Laurie[3] alludes to the possible danger from this gas but at the same time says he has "not been able to obtain evidence that the occasional exposure to small quantities of the gas has an injurious effect. While no marked symptoms follow the inhalation of small quantities of sulphuretted hydrogen, still it is more than likely that effects must in time follow the breathing of such a poisonous gas. Laurie's remarks apply mostly to persons living in the neighbourhood of chemical works and where the air, as at St. Helens, is occasionally polluted by the gas that escapes from the works. A very small quantity of sulphuretted hydrogen is sufficient to make itself known by its unpleasant odour. When men have been breathing H_2S for a time, and especially when mixed with other gases as in sewers, its presence is not so noticeable, and therefore the dangers attendant upon inhaling the gas are not realised. Gaseous emanations from sewers submitted to chemical analysis by Layet were found to contain sulphuretted hydrogen, ammonium sulphide, carbon dioxide, nitrous dioxide, and phosphoretted hydrogen. Herbert-Backer made a comparison between the various morbid phenomena due to prolonged exposure to air coming from sewers and showed the relationship of these phenomena to the different gases that were present. The sudden death of workmen in sewers is principally due to sulphuretted hydrogen. It is when sewers have got blocked and are being cleaned out that sudden fatalities have mostly occurred. In an ordinary way where there are only traces of this gas the workmen complain of vertigo, headache, and malaise, which disappear when the men come out into the fresh air, but occasionally it happens that a workman falls down in the sewer as if struck by an apoplectic seizure. On Feb 4th, 1862, four men were thus killed in a sewer under Fleet-street London. In 1880 in Paris five workmen were poisoned in a sewer in the Boulevard Roche-Chouart, of whom four died. In addition to sulphuretted hydrogen the air of sewers may be vitiated by carbon monoxide coming from illuminating gas that has escaped through a fissure in the pipes. Having escaped it is taken up by the soil and enters the sewers by aspiration, hence the necessity of a necropsy from a diagnostic point of view and of a spectroscopic examination of the blood of workmen who have died in the sewers. Since putrefying fæcal matter gives rise to sulphuretted hydrogen it should be remembered that empty cesspools are just as capable of causing mephitic poisoning as those that are full. In night-soil men the symptoms of the minor form of mixed sewer gas poisoning are complete and sudden loss of consciousness, immobility, and stiffness of the walls of the chest, respiration, while not entirely stopped, is irregular and incomplete, the pulse is scarcely perceptible, and the face and hands are pale, livid and cold. In the severer forms of poisoning convulsions occur, followed by death. When men have been rescued they have stated that they had experienced a sense of great weight about the lower part of their chest and a feeling as if their head had been tightly grasped in a vice.

Brouardel and Loye in 1885 showed that sulphuretted hydrogen destroyed life in two ways. In one form of poisoning death is *immediate*, *the individual falls down dead as if struck by lightning*. Death in these circumstances is clearly due to the action of the gas upon nerve centres, the pupil is dilated and its reflex is abolished, the limbs are firmly contracted respiration which is momentarily convulsed is soon arrested, the heart beats slowly and with this there is a gradual but regular fall of blood pressure leading up to death, the heart being the *ultimum moriens*. After death the blood is found to be dark and the hæmoglobin is practically speaking not altered. In the second form of poisoning death is slower. To the nervous phenomena there are added those due to asphyxia. After a preliminary phase characterised by dilatation of the pupil, insensitivity of the cornea, arrest of respiration, and slowing of the heart's action there appear symptoms due to asphyxia. Respiration recommences and for the moment the movements are energetic, all the muscles of the thorax and shoulders being brought into play. The heart meanwhile beats irregularly and the blood pressure falls or it rises and falls and the animal dies in a state of coma. The blood is very dark and its hæmoglobin is altered. The urine sometimes contains sugar or albumin."

Workmen who are exposed to the fumes of sulphuretted hydrogen occasionally complain, in addition to general feebleness and sense of weight at the stomach, of a skin eruption composed for the most part of small boils. Some men seem more predisposed to these than others.

It is difficult to say exactly how sulphuretted hydrogen kills. Wynter Blyth[4] says that sulphuretted hydrogen is distinctly a blood poison, the gas unites with the alkalies of the blood and the sulphides thus produced are partly decomposed in the lungs and breathed out again as sulphuretted hydrogen. Bouis,[5] on the other hand, is of the opinion that once sulphuretted hydrogen is in the lungs it finds itself under conditions that are most favourable for its transformation into sulphuric acid, and he therefore concludes that the disorders which it causes in these organs and in the blood ought to be attributed to this modification Hoppe-Seyler maintains that the gas absorbed acts upon the colouring matter of the blood and robs the hæmoglobin of its oxygen. A great deal depends upon the length of exposure to the gas and the amount of it present in the air that is breathed. Neither in the men who succumbed to the gas at Hebburn nor in the dog experimented upon in the laboratory did I find the hæmoglobin of the blood altered in any way J V Laborde, on the other hand, holds that sulphuretted hydrogen so acts upon the hæmoglobin that its presence in the blood determines a characteristic spectrum He is of the opinion that the gas acts mostly upon the nervous system. According to him sulphuretted hydrogen causes a functional arrest of the respiratory centre in the medulla. This effect may be brought about in two ways, directly or indirectly In the first, the poisonous gas when carried by the arterial blood to the brain acts upon the respiratory centre so as to induce disorder, it causes momentary arrest or it brings about in a more definite manner cessation of those functional phenomena which the centre superintends—viz., the mechanical respiratory movements. In the second mode a peripheral impression is made upon the pulmonary mucous membrane, or rather upon the terminal expansions of the vagal nerves in the lungs, whereby there is induced reflexly the same functional suspension By the latter method a fatal accident would be more immediate and more rapid since the gas would not require to be carried by the blood at all. Simple contact of the gas with the pulmonary mucous membrane would be sufficient to produce physiological effects.

[4] Poisons their Effects and Detection, third edition, p. 73.

In a paper of this length it is impossible to deal in detail with the chemical methods adopted to detect sulphuretted hydrogen, either qualitatively or quantitatively It is sufficient to state that if air containing the gas is aspirated through a solution of lead acetate a black colour is obtained Similar colouration is obtained on exposing filter paper moistened by silver nitrate or lead acetate solution

Is it possible to prevent such accidents as those that occurred at Hebburn? Excavations close to slag heaps or the waste refuse of chemical works should be conducted with the greatest caution Houses ought not to be erected in too close proximity to these heaps, for Taylor[6] reports that at Cleator Moor the inmates of some cottages that had been built upon iron slag rich in calcium and ferrous sulphide—three adults and three children—died during one night in consequence of a heavy rain washing through the slag and liberating a considerable quantity of sulphuretted hydrogen that found its way into the houses. It is dangerous, therefore, to allow buildings, especially for living in, to be erected close to either slag or chemical waste-heaps In all circumstances the odour of sulphuretted hydrogen should be regarded as a danger signal It is a fairly heavy gas, it has a density of 16 99, and is likely to lie low at the bottom of a cylinder or in a confined space. The freest ventilation is desirable, so as to prevent stagnation and to encourage the removal of the gas as far as possible. Before allowing men to work in confined spaces where there is a suspicion of sulphuretted hydrogen the plan might be adopted of exposing a piece of filter paper soaked in lead or silver solution A cylinder of oxygen should be at hand and in the event of apparent death from breathing the gas artificial respiration should be adopted at once in the open air, warmth applied externally, and stimulants with strychnine carefully administered

THE SURGICAL TREATMENT OF RHEUMATIC FEVER

By JOHN O'CONOR, M A., M D T C.D,
SENIOR MEDICAL OFFICER BRITISH HOSPITAL, BUENOS AYRES.

Since I first[1] invited attention to the necessity for surgical intervention in this disease I have been enabled further to test the value of the treatment in 20 cases, most of which, as may be seen on perusal of the notes, had proved recalcitrant to medical treatment. It would be puerile in a paper dealing with any treatment of this disease to pretend to ignore the high value placed on salicylic acid and its compounds by most competent medical observers, and while it is a duty to admit that many cases seem to derive benefit from its administration, yet a considerable number seem to be unaffected by it, and on many occasions I have witnessed the onset—indeed, establishment—of endocarditis during full physiological exhibition of the drug

In regard to a criticism passed on one of my early contributions on this subject that possibly such cases as had not reacted to salicylates were not rheumatism but a form of arthritis caused by some other infection, I can only state that such a distinction requires an empirical faith which I do not possess, particularly since I have proved that all these acute cases respond equally to an intelligent use of a scalpel Professor Osler in the latest edition of his work states that "the drug treatment of acute rheumatism is still far from satisfactory," and 'the truth is there are certain cases of rheumatic fever that resist all forms of treatment." If he should see his way to give surgery a trial I am confident that he will modify the last sentence in his next edition. At the same time I do not wish it to be understood that I consider my treatment a panacea in all forms of the disease. On the contrary, I have had proof[2] as to its futility in chronic cases, particularly in those of a dry variety, the result of prolonged pickling of synovial membrane and vessels in infective material But in the condition commonly understood as rheumatic fever, acute rheumatic arthritis, or acute rheumatism, I am certain that surgical treatment is most efficacious, not only in causing immediate disappearance of the arthritis and early cessation of general toxæmia, but also from effectually protecting the heart against attack.

In my first paper I ventured the clinical theory that this disease is an infective one, something similar to gonorrhœal arthritis and pyæmia, the germ or toxin gaining admission to the body through the tonsil or other microbial trapdoor, and that the joint invasion is promptly followed by a form of infective arthritis, accompanied with general toxæmia, and furthermore the infected joints serve as incubators where the poison is elaborated and passed into the circulation, and thus conveyed to other articulations and to the heart. Having such views I maintain that removal of the infective material as soon as possible from the infected joints is a scientific and rational method of treatment, a conclusion fully corroborated by results It is hardly necessary to observe that, as in pyæmia and gonorrhœal arthritis,[3] the extent or intensity of metastatic lesions may be out of all proportion to that of the primary focus of infection, yet no matter how trivial the signs of the latter may seem, it is necessary to deal radically with it before hoping effectually to overcome the former I wish again to invite attention to the form of infective watery cellulitis[4] which not infrequently appears to be the dominant manifestation of the disease about the ankle and wrist joints. Sometimes I find this associated with evidence of arthritis of the corresponding joints and sometimes not Multiple incisions effect a prompt cure

Case 1.—A man aged 41 years was admitted to hospital on June 21st, 1897, suffering from rheumatic fever, the symptoms being a temperature of 102° F, the tongue thickly coated, the pulse 80, profuse sweating, anorexia, the urine scanty and high coloured, with a trace of albumin There was slight pain in the left elbow but no swelling was visible th knee joints were swollen, and the patellæ were floating d very painful, with some peri articular inflammation and ght œdema. There were no cardiac complications. Not-thstanding a liberal and prolonged trial of salicylate of la, salicin, turpentine, quinine, and flannel to the joints. nkets, and milk diet the case gradually assumed an ynamic character, and as he could not be got to take urishment by the mouth nutrient rectal enemata were ad-nistered. Blisters, fomentations, ointments, iodine, even seed poultices were in turn applied locally but no treat-ent, internal or external, seemed to diminish the quantity fluid in the knee-joints or general toxæmia. As a last source, on July 17th, arthrotomy of the right knee was rformed and four ounces of turbid serum with many large asses of lymph were removed. Owing to his low condition could not perform arthrotomy of the left knee until three ys later when some six ounces of similar stuff were acuated All constitutional symptoms rapidly disappeared ter the latter operation and he was discharged with good ovement in both joints on Sept. 17th. A year later he ported himself and his condition was found to be normal.

[4] Annals of Surgery April 1899

CASE 2 —A man, aged 59 years, was admitted to hospital n Nov 12th, 1897, suffering from acute infection of both nee-joints with a temperature of 103° F, *profuse sweating,* blankety tongue, scanty high-coloured urine, constipation nd anorexia. As the orthodox medical treatment showed no ndency to reduce the swelling of the knee-joints or to relieve he general toxæmia double arthrotomy was performed on ov 18th. Three and a half ounces of flocculent serum were emoved from the right knee and four from the left Drain-ge with irrigation was continued for four days. Consti-utional symptoms vanished, he was allowed out of bed on ov 28th, and he was discharged cured on Dec. 6th

CASE 3.—A man, aged 40 years was admitted to hos-ital on Dec. 16th, 1897 suffering from rheumatic fever he temperature was 101 4° F, the tongue was furred, here was profuse sweating, and the urine was scanty, igh-coloured, and albuminous He complained of intense ain with stiffness in the left ankle, right knee, and left lbow There was considerable peri articular inflamma-ion about the ankle, the knee was much distended, im nobile, and painful to touch, and the elbow was swollen, ixed, and tender Sodium salicylate was administered in 20-grain doses every two hours, the joints were enveloped in lannel and liquid diet was given. As no improvement took lace on Dec. 18th the left ankle-joint was opened, nothing ut a small quantity of synovial fluid was found, multiple ncisions were then made through the swollen and inflamed peri articular structures, the cellular tissue was freely opened up, and the wounds were irrigated and packed with gauze. The right knee joint was then opened and six ounces of green turbid (almost purulent) serum were removed. Many lymph flakes were detached by the finger from the recesses of the joint and were removed by irrigation and free drainage was provided. Arthrotomy was finally performed on the left elbow and a tablespoonful of dirty serum was removed, followed by irrigation and drainage. On the third day the temperature fell to and remained at, normal, he partook of a full meal on Dec. 25th and was discharged cured on Jan. 10th, the joints being normal in contour and function.

CASE 4 —A man, aged 43 years, a workman, was suddenly taken ill on Nov 25th, 1897 with fever and shivering pain and swelling in both wrists, and a few days later both knees became similarly involved. He continued under the care of his family medical attendant until Dec. 6th when he sought hospital treatment. On admission his temperature was 102° F with all the usual symptoms of rheumatic fever, both wrists were red tender swollen, and stiff, and the left knee was distended and flexed. Salicylates, flannel, and milk diet were most assiduously tried until the 19th and as the condition, local or general had in no way improved both wrists were opened No abnormal fluid was found, but on making multiple incisions into the adjacent area affected with cellulitis a quantity of serum escaped from each wound. Arthrotomy was then performed on the left knee and some two ounces of turbid serum were evacuated. The temperature continued normal after 48 hours the joints rapidly resumed their normal condition, and he was discharged cured on Jan. 11th.

CASE 5.—A man, aged 40 years, was admitted to hospital on Feb. 24th 1893. His history was that ten months previously he caught cold" and suffered from pain and swelling in the left hand and wrist. These symptoms gradually disappeared without treatment. Three months later pain returned in the wrist and two months afterwards the left ankle and foot became swollen and stiff and for the succeeding five months he was unable to walk. On admission his temperature was 99 3° F, his tongue was furred, and there was some sweating, his urine was scanty and high-coloured, he had anorexia and he presented a worn-out appearance. The left ankle and foot were swollen, red, tender, and stiff, any attempt at passive movement caused intense pain. The left wrist was in a similar condition, there was no pain or swelling in any other joint, he had no organic disease The gums were healthy and he had not suffered from colic, he had had gonorrhœa 15 years before. On Feb 26th the dorsum of the left foot was incised, the cellular tissue was freely opened up, and the ankle and three tarsal joints were explored. A considerable quantity of serum oozed from the cut tissues, but the interiors of the joints were normal. The wrist received identical treatment, there was no fluid found in the joint (radio-carpal) On the fifth day the general symptoms had disappeared, there was free and painless movement in both articulations, and the patient asked for solid food. On the twenty-fourth day he was discharged cured Before leaving the hospital he ran 90 yards on a tiled floor his feet being bare, without a limp or ache

CASE 6.—A man, aged 26 years, a sailor, entered hospital on March 1st, 1898, with the following history On Feb 14th he caught cold on board ship and soon afterwards he felt pain in the left ankle. On the following morning his left knee became swollen and painful, accompanied with fever, "dry" tongue, loss of appetite, and scanty dark coloured urine. On admission the temperature was 100° F, the tongue was furred, and the left knee was considerably distended, the patella was floating, with marked tenderness and pain on movement The left ankle appeared to be normal. There was no organic disease. The patient had had gonorrhœa five years previously On March 2nd arthrotomy was performed and six ounces of greenish turbid flocculent serum were removed from the affected knee. Irrigation and drainage were carried out for three days On March 28th he was discharged cured and fit for work

CASE 7 —A man, aged 46 years, a labourer was admitted into hospital on March 1st. 1898, with the following history On Feb. 22nd he slept in wet hay and caught a severe cold. On the following day his right knee and right ankle became swollen, stiff, and painful. On the 27th the left knee became similarly affected. On admission his temperature was 101°F, he had a dirty tongue, profuse sweating was present and the urine was scanty and high-coloured, both knee-joints were distended, flexed, and tender to the touch. The right ankle and dorsum of the foot were swollen, red, and painful. There was no organic disease. On March 2nd three long incisions were made on the dorsum of the foot, serum oozed from the cut surfaces, nothing abnormal was found in the ankle-joint Arthrotomy was then performed on both knee joints four ounces of the usual muddy serum being removed from the right and two ounces from the left. On the third day all symptoms of general toxæmia had disappeared The patient was allowed out of bed on March 14th and was discharged cured on the 30th.

CASE 8.—A man, aged 27 years. a sailor, was admitted into hospital on April 23rd, 1898, with the following history On April 18th he caught "a severe cold on board ship On the 19th the left knee and the left foot suddenly became swollen and very painful, accompanied with fever sweats, shivering, constant cough, and difficulty in breathing On the 21st the right knee and right foot became similarly affected and on the 22nd pain and swelling commenced in the right shoulder On admission the patient presented a livid appearance His respirations were 38, his pulse was 110, and his temperature was 101° F, his tongue was furred and dry, he was bathed in perspiration, both lungs were extensively affected with bronchitis with slight basic congestion and abundant muco-purulent sputum, and his urine was high coloured and albuminous. The right shoulder was fixed swollen, and tender both knees were distended, painful and immobile, and the dorsum and sides of both feet and ankles were extremely inflamed and painful. The fact of his heart having so far escaped led me to take the pulmonary risk in a young sailor A small amount of chloroform was administered and within 20 minutes I returned him to a warm bed with free drainage of the above five joints having also incised and drained areas of cellulitis. Thanks to excellent nursing and free stimulation by hypodermic injections of strychnia and digitalis and rectal injections of hot coffee and brandy with frequent inhalations of oxygen gas, he steadily recovered from operative shock On the third day the dressings were changed. The wounds were healthy, there was slight, painless, active motion in each joint, but the swelling was considerably decreased, the tongue was moist, the respirations were 30 and the bronchitis was improving There was no cardiac complication On the sixth day he was given full diet. As his condition permitted of it he was placed in an armchair before a fire for an hour 14 days later he was walking about with normal joints, no trace of rheumatism having reappeared in any part of the body An uneventful convalescence ensued I think there are few who will not admit that this case was another triumph for Lord Lister

CASE 9 —A man, aged 42 years, a labourer, was admitted to hospital on May 6th, 1898, with the following history On the night of April 25th, while sleeping in a draughty hut, he caught cold, accompanied with fever, shivering, and sweating On the following day he felt acute pain in both wrists next day both feet became painful and on the 28th the left foot became swollen, tender to touch and very painful to move. On May 1st pains had ceased in the wrists and right foot but the condition of the left foot became more intensified On admission on the 6th his temperature was 99° F, his tongue was moist and furred, and the dorsum and sides of the left foot were swollen and very much inflamed With regard to his past history he had never had any serious illness and although he stated that he suffered from gonorrhœa two months previously no evidence of the same could be elicited by repeated examination of the penis during his stay in hospital, however there was a suspicion. On May 7th, assisted by my friend Dr L Colbourne of Beckenham five four inch incisions were made into the area of tumefaction, the tissues appeared to be waterlogged and serum poured out of them when divided, the ankle joint was explored but nothing abnormal was found A rapid and permanent recovery ensued

CASE 10 —A man, aged 44 years, was admitted to hospital on Feb 6th, 1899, suffering from rheumatic fever Both knees were considerably distended, painful, and stiff, and both the ankles and the dorsum of each foot were swollen, red, and painful His temperature was 102 6 F, his pulse was 100, his tongue was furred and he had profuse perspiration His urine was scanty and contained urates and a trace of albumin As to his past history he had had two attacks of rheumatic fever, the first in 1882 and the second in 1888 with occasional attacks of joint pains in the intervals. On Feb 7th arthrotomy was performed on both knees, 12 ounces of turbid fluid were removed from the right knee and four from the left, followed by irrigation and drainage Multiple incisions were made into the area of cellulitis about the ankles, no fluid was found in the joints An uneventful convalescence ensued and the patient was discharged cured on March 31st.

CASE 11.—A man, aged 30 years, a labourer, was admitted to hospital on July 19th, 1899 His temperature was 102° F, with great thirst and sweating His left ankle was swollen and inflamed Two days later both knee-joints and the other ankle became swollen and tender His urine was scanty and full of urates On the 23rd arthrotomy was performed on both knee joints and turbid, flaky serum was evacuated from each Multiple incisions were made in the feet, no fluid was found in the ankle joints Convalescence immediately followed and the patient was discharged cured on Sept. 6th.

CASE 12.—A man, aged 30 years, a coachman, was admitted to hospital on May 23rd, 1899, suffering from an injury to the right knee caused by a fall in the coach house two days previously The joint was found to be considerably distended and somewhat discoloured with some pain on movement. A diagnosis of traumatic hæmarthrosis was made. There were general symptoms. On the 25th the usual arthrotomy[5] was performed and six ounces of dark blood and clots were evacuated from the joint The wound gradually closed, the joint resumed its normal contour, and the patient was allowed out of bed on the eighteenth day On June 23rd he suddenly complained of feeling very ill, with fever and shivering The temperature suddenly rose to 102 3° F Two days later the left knee, both ankles, and the right wrist became swollen, stiff and painful, accompanied with profuse sweating, dry furred tongue, and scanty, high coloured urine. On the following day his respirations were noted to be 34 per minute, with some cyanosis, and a pericardial friction sound was distinctly audible. His temperature was 103° and his pulse was 110 A diagnosis of rheumatic fever was made Soda salicylate was given in 15-grain doses every two hours, the patient was placed in blankets, the joints were enveloped in flannel, and the patient was given a milk diet This treatment was continued for one month, but as no improvement took place, either locally or generally, he became extremely emaciated On July 25th arthrotomy was performed on the left knee and some four ounces of green flaky serum were removed Both ankle joints were opened, each containing about a teaspoonful of turbid fluid, and the swelling around the wrist was freely incised. On the following day on entering the ward it was evident that the right treatment had "at last" been adopted the patient felt much better An uninterrupted convalescence ensued and he was discharged cured on August 25th The joints and pericardium were normal.

CASE 13 —A man, aged 48 years, was admitted to hospital on Nov 14th, 1899, suffering from rheumatic fever His temperature was 100 5° F, he was sweating, had a furred tongue, and complained of great pain in the affected joints, the right wrist, the right shoulder, the left ankle, and the palmar surfaces of eight fingers. For three weeks previous to admission he had been under the care of his family medical attendant, who kept him between blankets, enveloped the joints in warm wool, and administered constant doses of soda salicylate. On admission he was in a most miserable condition, he was generally painful, had anorexia, and was emaciated Altogether he was a most unpromising patient. On the 15th arthrotomy was performed on the wrist, shoulder and ankle, which I supplemented with incisions in the swollen tissues, I also freely incised the inflamed eight fingers On the following day he expressed himself as feeling much relieved The symptoms gradually disappeared, he partook of full diet on the tenth day, and was discharged cured on Jan. 13th. He has frequently reported himself and there has been no relapse.

CASE 14 —A boy, aged 15 years, was admitted into hospital on Feb 7th, 1900, suffering from rheumatic fever, which commenced suddenly six weeks previously with chills and fever and pain and swelling in the right knee and left big toe. On admission the temperature was 100° F, the tongue was furred, and the patient appeared to be very anæmic. The right knee was slightly swollen and was tender on palpation, and the dorsum of the left great toe was swollen and inflamed Two days later arthrotomy was performed on the knee, and a few ounces of green turbid serum were removed An incision was made into the swelling on the toe and serum exuded. On the third day, while the knee and the toe were normal except for wounds, some swelling was noticed and pain was complained of in the right wrist. Chloroform was at once administered Three incisions were made on the dorsum of the wrist and about a drachm of flaky serum was removed from' the radio-carpal joint, into the latter a small gauze drain was inserted. The patient afterwards confessed he had noticed that his wrist was bad before the first operation, but thought that "it did not matter" On the tenth day he was allowed out of bed and he was discharged cured on the eighteenth day

CASE 15 —A boy, aged nine years, was admitted into hospital on Oct. 18th, 1900, with swelling and pain in both knees and ankles. His temperature was 102° F, his pulse was 118, and his tongue was covered with white fur With regard to the heart, the apex was in the nipple line, fifth interspace, there was increased dulness to the left, the first sound was reduplicated and the pulmonary second sound was markedly accentuated A systolic murmur was distinct at the apex, audible along the left sternal border, and also in the axilla Treatment was as follows Sodium salicylate, 10 grains every four hours, was given with blankets flannel, and a milk diet. No improvement followed and on the 21st both knees were opened and greenish flaky serum was evacuated from each Multiple incisions were made on the feet. No abnormal fluid was found in the ankle joints. Rapid recovery ensued The patient was allowed out of bed on the twenty fifth day and was discharged cured a week later Unfortunately no note was taken of the cardiac condition before discharge

CASE 16.—A man, aged 28 years, was admitted into hospital on Oct. 31st, 1900, suffering from rheumatic fever The right knee was distended very tender, and painful, and the left ankle and dorsum of the foot were swollen and tender There was also some swelling noted, nd pain was complained of, in the left knee and right ankle he tongue was furred, the skin was moist, and the tem erature was 101 6° F On the following day arthrotomy of oth knees was performed and about four ounces of flaky erum were removed from the right, and about two ounces rom the left, knee joint, irrigation and drainage were per ormed as usual Multiple incisions were made into the rea of cellulitis around the ankles, these joints did not con ain any abnormal fluid. On the thirty second day the atient was discharged cured

---

[5] Traumatic Hæmarthrosis of the Knee-joint New York Medical Journal 1896.

CASE 17—A man, aged 30 years, was admitted into ospital on Feb 2nd, 1901, suffering from rheumatic ever His temperature was 101 6° F, his pulse was 94 is tongue was furred, he had acid sweats, and the left nee was swollen and painful. Sodium salicylate was given very three hours in 10-grain doses, and he was placed in lankets and the joints were fomented. On the 5th the ight knee and both ankles became swollen The tempera ure reached *102 4° at night. On the 7th* arthrotomy of oth knees was performed and the usual dirty greenish luid was removed. Multiple incisions were made *into* the area of cellulitis on the dorsum of the feet, the ankle-joints were opened and some turbid serum was found in each On the 14th he was allowed out of bed, he had normal movement in the joints and the wounds were granulating On the twenty eighth day he was discharged cured.

CASE 18—A man aged 34 years, a labourer, was admitted into hospital on Feb 26th 1901, complaining of pain and swelling in the left wrist and left ankle, which had commenced suddenly on the 19th. On *admission* his temperature was 101° F, his tongue was furred, he had profuse sweating, and the left wrist and left ankle were swollen, red, and tender He was treated for eight days on salicylate of soda, rest in *bed* flannel, and milk diet. No improvement followed, and on the ninth day multiple incisions were made into the area of cellulitis on the back of the wrist. A quantity of serum escaped. The radio-carpal joint was opened and a little turbid flaky fluid was removed. Multiple incisions were then made into the *area of cellulitis around the* ankle No abnormal fluid was found in the joint. On the third day the dressings were changed, the drain was omitted from the wrist the wounds were quite aseptic, pain had vanished, and the swelling was considerably decreased. On the thirtieth day he was discharged cured.

CASE 19—A man, aged 27 years, was admitted into hospital on August 11th, 1902, suffering from rheumatic fever There was a strong family history the father mother, and sisters having suffered *from* rheumatism. On admission his temperature was 100° F, *his tongue* was furred, and he was very pale. Both his knees were swollen, stiff, and painful. The left ankle was very painful, red, and swollen. His urine was scanty His heart was normal. Sodium salicylate was given him in 10-grain doses every three hours The joints were painted with iodine and wrapped in wool and blankets and a fluid *diet* was given. A week later the right ankle became swollen and painful. The above treatment was persevered with until Sept. 11th, when it was obvious that the patient was gradually becoming more debilitated, the joint symptoms remained at a standstill, with continuous moderate general toxæmia Arthrotomy was performed on both knees and some turbid flaky serum was removed *from each.* The ankle-joints were opened and about a teaspoonful of similar stuff was removed from each, the area of cellulitis around the latter joints being freely incised. On the following day all pains had vanished, the toxæmia gradually got less he was allowed out of bed on Oct. 1st, and he was discharge cured and fit *for* work 14 days later

CASE 20—A youth, aged 18 years, was admitted to hospital on Sept. 25th, 1902, *suffering* from rheumatic fever His temperature was 101° F, he had severe headache, anorexia, furred tongue, and pain in the shoulders, both knees were distended and painful. The heart was *normal.* Medical treatment was given as before Four days later the right wrist became swollen, red, and painful, and on the following day both ankles became similarly affected. With regard to the heart cardiac dulness increased outwards and down wards the apex beat was in the fifth space in the nipple line, the pulmonary second sound was much accentuated, and a rough systolic bruit was distinctly audible in the fourth interspace, at the apex and in the axilla On the 30th arthrotomy was performed in both knees and the right wrist and some turbid serum was removed from each. An extraordinary improvement immediately followed. After the third day all general symptoms had vanished and the joints were painless and normal in contour On Oct. 11th a full diet was ordered, and the patient was allowed out of bed on the following day, and two days later was walking about in a garden. I very much regret that the cardiac examination on the 13th still revealed a loud blowing systolic murmur at the apex, conducted round to the back, and another (probably hæmic) systolic murmur was heard in the second left interspace near the sternum. I have no hesitation in *stating* that *this patient's heart* has been practically ruined through my delay in operating, for I have no doubt that if I had performed arthrotomy on both knees on *Sept 26th* the infection would have ceased. As I stated before it is not the first occasion on which salicylic acid has proved worse than useless in my experience.

While *advocating* early surgical interference in rheumatic fever I cannot too strongly deprecate any attempt at the same without the operator feeling assured that he commands all the ordinary essential elements with which to carry out an ordinary aseptic operation It is obvious that under *septic conditions this method of* cure might readily be attended with greater disasters than might even originate from the disease itself. To anyone about to put my practice to the test may I suggest (1) do not puncture, open knee-joints, (2) ligate all bleeding points, and (3) drain, do not cork Also I *wish to insist on* the great value of thorough drainage in these cases, for it would be a more imbecile act to close a joint containing such toxæmic stuff than to seal hermetically a recent ischio-rectal abscess cavity In order to carry this properly into effect in operations on the knee-joint an incision an inch *long* is made on each side of the joint through the capsule. Through both openings a long closed forceps is passed and a fenestrated india rubber tube half an inch in diameter is drawn across the synovial pouch, leaving about half an inch of tubing presenting at each wound Drainage having been thus secured the joint is washed out every morning with a jugful of warm carbolic lotion (1 in 60) and the tube is generally dispensed with on the third or fourth day Irrigation of the joint is daily continued until healing no longer permits of the passage of fluid A little *superficial necrosis of wound tissue caused by* pressure of the drainage-tube need not excite alarm, as this rapidly disappears under an iodoform gauze *dressing* The latter, by the way is made fresh for each dressing by immersing pieces of dry sterilised gauze in a solution of equal parts by weight of iodoform, alcohol, and glycerine. A little formalin (1 in 500) is added to the mixture before use In arthrotomy of the wrist- and ankle-joints drainage is attained by a piece of gauze passed into the joint through the open blades of a dressing forceps previously inserted

Buenos Ayres.

THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS

BY H. HYSLOP THOMSON, M D GLASG,
RESIDENT PHYSICIAN CONSUMPTION SANATORIUM BRIDGE OF WEIR N.B

SUCCESS in the sanatorium treatment of pulmonary tuberculosis depends largely upon the care exercised in the selection of suitable cases, for in proportion as the disease advances beyond the initial stage of infiltration the chances of ultimate recovery become lessened In the majority of cases of uncomplicated tuberculous pulmonary disease, if treatment be commenced during the stage of infiltration and afterwards continued as a precautionary measure the result will assuredly be a complete and permanent arrestment of the morbid condition, the prolongation of life, and the securing of health and comfort. And not only so, but the benefit which accrues from the early isolation of tuberculous patients in sanatoriums is not limited to the sufferers alone, it is extended to the community at large, as in every case under treatment a *possible focus* of *infection* is removed from amongst a larger or smaller circle of people.

The diagnosis of pulmonary tuberculosis in *its early stage* is not always an easy matter Its existence cannot always be confirmed by the detection of tubercle bacilli in the sputum, as frequently expectoration is either absent or it consists of mucus which seldom gives positive results on examination Further, physical signs of disease implicating the lungs may be so indefinite as to be easily overlooked, while the cardinal symptoms of phthisis at this stage are not generally well developed

In considering whether a patient is or is not suffering from early tuberculosis of the lung it is desirable, before proceeding to the examination of the chest, to make a careful inquiry into the family and personal history Due consideration must be given to the existence of a tuberculous family history as pointing to an inherited predisposition or the probability of exposure to infection The presence of a pre existing pleurisy, a history of hæmoptysis, or the evidence of tuberculous disease of the cervical lymphatic glands should be noted That these points are worthy of consideration in relation to diagnosis a glance at the subjoined figures will show Out of 170 patients examined the following numbers were obtained a tuberculous family history in 39 per cent., a history of pleurisy in 25 per cent. , a history of hæmoptysis in 31 7 per cent. , and evidence of lymphatic disease in 12 per cent The nature of onset of the patient's present illness should be carefully inquired into as it may shed some light upon the diagnosis to be subsequently made

As indicated by the figures given above, a "hæmorrhagic onset" is characteristic of a fair proportion of cases, the disease being ushered in by a somewhat sharp hæmoptysis, prior to which little or no complaint of ill health was made. Frequently the onset is more gradual, the patient complaining of such symptoms as anorexia, slight loss of flesh, occasional night sweating, cough with or without expectoration, and some diminution of strength But this is not always so In some cases of early phthisis the pulmonary symptoms are masked, the only evidence of disease being dyspepsia, occasionally with morning sickness, or anæmia, and thus the onset of the disease is so insidious as to escape the watchful eye of the most anxious guardian On the other hand, an acute or subacute onset is met with, the disease being ushered in with symptoms which may be indistinguishable from those of acute pleurisy or influenza. After what may be a varied period of indifferent health the patient is suddenly seized with pleuritic or muscular pains, pyrexia, occasionally with rigors, malaise, headache, night sweating cough with or without expectoration, and loss of flesh In such cases the termination may be rapidly fatal, or the acute symptoms may subside and some measure of improvement follow but the physical signs of pulmonary disease remain.

Before proceeding to the consideration of the various physical signs met with in the early stage of pulmonary tuberculosis it is necessary to bear in mind the sites primarily selected for the deposition of tubercle. The peribronchial, perivascular and subpleural tissues and the walls of the lung alveoli are the regions first invaded, and consequently the physical signs indicative of the early stage are referable to the presence of disease in one or other of these situations.

In cases characterised by early hæmorrhage there is invasion of the perivascular tissue by tubercle, although it does not necessarily follow that in all cases of perivascular infiltration there is hæmorrhage. A careful and methodical examination of the various regions of the chest must always be made. Inspection may reveal the presence of flattening, diminished movement, or muscular wasting over some particular region of the chest wall. Overend emphasises the diagnostic significance of venous varicosities in the cervico dorsal region in early pulmonary tuberculosis and in a certain number of cases they are present, but they are more frequently associated with some degree of consolidation of the lung tissue The deposition of the tuberculous nodule at one or other apex may give rise to some appreciable diminution of the normal percussion resonance. The apices should be lightly percussed during ordinary respiration, full inspiration, and forced expiration Over the supra and sub-spinous fossæ percussion should be more forcibly employed and the interscapular, subscapular, and axillary regions must also be carefully percussed. The condition of the tactile vocal fremitus and the voice resonance as appreciated by palpation and auscultation must be carefully noted Increased vocal resonance at the left apex, as compared with the right, is of greater significance than the converse Deviation from the normal in the quality of the respiratory murmur is, perhaps, the most constant physical sign in early tuberculosis of the lung The mechanical effect following the infiltration of the interstitial lung tissue with tubercle is twofold There is narrowing or occlusion of the lumen of some of the finer bronchi from pressure, while the normal expansion and relaxation of the elastic pulmonary tissue are interfered with and the ingress and egress of air are interrupted Consequently the respiratory murmur may be feeble or entirely absent at one or other apex It may be jerky and irregular in character, the irregularity affecting inspiration or expiration alone or both together Some degree of irregularity of the respiratory murmur is occasionally present in nervous people while undergoing examination, but it is usually to be heard over the greater part of the lung area. When audible over a circumscribed area, and more especially when involving expiration, it points to invasion of the lung tissue by some morbid process With a feeble inspiratory murmur there may be prolonged and harsh expiration or the respiratory murmur as a whole may be harsh in quality with expiration unduly prolonged The adventitious sounds heard during the early stage of pulmonary tuberculosis depend for their presence upon the tissues primarily invaded by tubercle. Over the supra spinous fossa and upper portion of the scapular region in a certain proportion of cases there is pleuritic friction with some diminution of percussion, resonance, and accentuation of the vocal resonance This is the only evidence of disease present and presumably points to the subpleural deposition of tubercle. The constriction of the finer bronchi by nodules in the peribronchial tissue will give rise to the presence of rhonchi from narrowing of the lumen or the production of bronchitis. Sibilant or sonorous rhonchi during inspiration, or accompanying a prolonged expiration heard over a restricted area of lung tissue, more especially if associated with increased vocal resonance should always be regarded with suspicion. Sibilant rhonchi are generally audible towards the end of inspiration, while those accompanying expiration are invariably lower in pitch The detection of râles, however, is of greater importance In many cases they are absent or so faint as to be almost inaudible , when present they occur during, or at the end of, inspiration, are fine in quality, and clicking or crepitant in character A few cases are met with in which crepitant râles with feeble respiratory murmur are the early and only signs present and in which it may be presumed the walls of the lung alveoli are primarily invaded.

The presence of some of the physical signs mentioned above should not be regarded as sufficient in themselves to constitute a diagnosis of commencing pulmonary tuberculosis In all suspicious cases the morning and evening temperature should be regularly recorded for a period of three weeks, so that any rise of temperature may be noted. A continuous evening rectal temperature reaching above 99° F would point to the probability of tuberculous disease. The absence of pyrexia, however must not be taken as contra indicating the possibility of phthisis, as disease in the early and more advanced stages may be present without any appreciable rise in temperature. In doubtful cases a reaction to Koch's tuberculin should be sought for A local inflammatory reaction and a definite rise in temperature should follow the injection of tuberculin in tuberculous subjects. Either tuberculin may be used, but the new tuberculin in doses of from half a milligramme to one or two milligrammes will be found to induce sufficient reaction for diagnostic purposes. Before employing tuberculin the temperature should be taken morning and evening for a period of not less than 14 days While being subjected to the test the patient must remain in bed, and should the first dose fail to produce a reaction three days must be allowed to elapse before an increased dose be given. A rise in temperature of not less than 1° F should be obtained before the diagnosis of pulmonary tuberculosis be made The following cases illustrate the utility of tuberculin.

CASE 1.—The patient was admitted into the Consumption Sanatorium at Bridge-of-Weir on Jan 21st, 1902, with a history of cough without expectoration and occasional night sweating There had been slight hæmoptysis on one occasion, with some loss of flesh and strength of several months' duration No particulars of the family history were obtainable There had, however, been exposure to infection, as the patient had slept for four or five months with a companion suffering from pulmonary tuberculosis On admission the patient was found to be well nourished but anæmic The temperature was 98 8° F , the pulse was 83, and the respirations were 20 The weight was 8 stones 5 pounds 10 ounces The chest measured 30 inches. The right clavicle was more prominent than the left. Over the right supra clavicular and infra clavicular fossæ movement was impaired, tactile fremitus and vocal resonance were increased, and percussion resonance was diminished The respiratory murmur was feeble and a sharp clicking rale was occasionally heard above the clavicle. Over the right supraspinous fossa and right scapular region there was prolonged expiration with increased vocal resonance while over the scapular region alone pleuritic friction was audible. A dose of half a milligramme of the new tuberculin was injected, with due antiseptic precautions into the left interscapular region On the following day the temperature rose 2 4°, reaching 101 2°

CASE 2 —The patient was admitted into the sanatorium on May 24th, 1902, with a history of cough without expectoration, night sweating hæmoptysis, loss of flesh, and diminution of strength of five years' duration As regards the family history, the father had died from some pulmonary disease the nature of which was unknown. On admission the patient was found to be fairly well nourished but somewhat anæmic. The temperature was 98 8° F , the pulse was 64, and the respirations were 20 The weight was 8 stones 4 pounds 10 ounces The chest measured 30 inches The left clavicle was more prominent than the right. Over the left supra-clavicular and infra-clavicular fossæ movement was impaired, the percussion note was distinctly hyper resonant, and the respiratory murmur was feeble and indistinct. In the left mammary region fine crackling râles were audible A dose of one milligramme of tuberculin was injected into the left forearm. Next day the temperature rose 5°, reaching 103 6°

CASE 3 —The patient was admitted into the sanatorium on April 10th, 1902, with a history of cough without expectoration and loss of flesh of four months duration. As regards the family history, two sisters had died from pulmonary tuberculosis. On admission the patient was found to be thin but of good colour The temperature was 98 6° F , the pulse was 70, and the respirations were 18. The weight was 6 stones 12 pounds 4 ounces. The chest measured 30 inches. There was no limitation of movement or any appreciable diminution of percussion resonance. Over the right supra clavicular and infra-clavicular fossæ inspiration was jerky Over the left supra clavicular fossa and immediately below the left clavicle inspiration was jerky and expiration prolonged and wavy in character, while at the end of inspiration a sharp clicking râle was occasionally audible. Over the left supra spinous and scapular regions the respiratory murmur was harsh A dose of a quarter of a milligramme of tuberculin was injected into the left inter scapular region. Next day the temperature rose 2°, reaching 100 2° F

CASE 4 —The patient was admitted into the sanatorium on May 24th, 1902, with a history of cough with expectoration and occasional night sweating with loss of flesh and appetite and increasing weakness of six months' duration No particulars of the family history were obtainable. On admission the patient was found to be fairly well nourished and of good colour The temperature was 99 6° F , the pulse was 76, and the respirations were 24 The weight was 8 stones 1 pound. The chest measured 30½ inches There was some flattening beneath the right clavicle. Over the right supraclavicular and infra clavicular fossæ percussion resonance was diminished, vocal resonance was increased, and the respiratory murmur was feeble and indistinct. Over the right supra spinous and scapular regions the respiratory murmur was feeble and fine crackling râles were audible. The left lung appeared normal. No tubercle bacilli were found in the sputum A dose of one milligramme of tuberculin was injected into the left forearm Next day the temperature rose 5 8°, reaching 104°

CASE 5 —The patient was admitted into the sanatorium on May 1st, 1902, with a history of cough without expectoration breathlessness on exertion, and occasional night sweating, with loss of flesh and appetite of six months duration The mother had died from pulmonary tuberculosis. On admission the patient was found to be of good colour and well nourished. The temperature was 99° F , the pulse was 77 and the respirations were 16 The weight was 9 stones 7 pounds 4 ounces. The chest measured 30½ inches At the right apex percussion resonance was diminished, vocal resonance was increased and expiration was prolonged. Over the left subscapular and infra axillary regions the percussion note was relatively dull the tactile vocal fremitus and the vocal resonance were diminished and the breath sounds were feeble pointing to the effusion of fluid which was confirmed by paracentesis. A dose of a quarter of a milligramme of tuberculin was injected into the right interscapular region. On the following day the temperature rose 1 8°, reaching 100 2° The local inflammatory reaction in this case was severe.

A brief consideration of the pathology of the various stages of pulmonary tuberculosis will emphasise the importance of early diagnosis in relation to successful treatment. The early stage is characterised by the simple presence of tubercles In the intermediate stage there is pneumonic consolidation of considerable areas surrounding the tubercles, while the process of necrosis with softening is commencing in the tubercles themselves The vitality of the tissues is necessarily compromised and arrestment of the morbid condition will seldom, if ever, take place except by the expulsion of the necrosed tissue and the formation and subsequent contraction of a clearly defined excavation. On the other hand, in the presence of comparatively healthy lung tissue and recently deposited tubercles the formation of healthy granulation and cicatricial tissue can under treatment be more readily induced and the stage of complete arrestment more speedily reached

In conclusion, it may be confidently anticipated that if combined with prophylactic measures there be an earnest endeavour to diagnose existing cases of pulmonary tuberculosis in the early stage and submit them to immediate treatment a definite diminution in the prevalence of the disease will result and the prospect of increased health to the future manhood and womanhood of our country will be assured

Bridge-of-Weir N.B

DIRECTIONS FOR PHOTOMICROGRAPHY.

By FRANK CROSBIE.

CONSIDERING the great increase in the use of photography during the last few years it is strange that photomicrographs have not been more generally produced. The cause of this probably lies in the supposition that the process is necessarily very difficult and the apparatus expensive This is not the case, and anyone who can develop an ordinary negative can readily produce photomicrographs of a high class, the cost and difficulty being no greater than that of ordinary photography A box camera that will work in conjunction with the microscope must be constructed. This is not difficult and any joiner or skilled amateur can soon make a light-tight box for this purpose at the cost of very few shillings. The camera shown in the illustration (Fig 1) consists of a box supported by four uprights, connected finally to a heavy platform. The whole is made of stout deal stained mahogany colour, and the box is blackened inside a 'dull black." It is so constructed that the top end of the box is adapted to take the detachable reversing back of an ordinary quarter plate camera. Duplicate fittings can usually be obtained from the maker of any quarter plate camera. At the lower end of the box is an aperture pierced in its floor, fitted with a moveable union to connect it with the microscope which stands on the platform beneath The distance between the bottom of the camera box and the platform should be about an inch more than the height of the microscope, after the draw tube has been removed, in order to facilitate removal and readjustment of the microscope. The length of the camera box and therefore the amplification obtainable is limited by the possibility of reaching the focussing screws and the mirror of the microscope when the operator is seated on a chair looking down through the compound focusser on to the focussing screen at the top end of the box. In other words, the total height of the camera is governed by the length of arm of the seated operator The union that connects the lower end of the camera box to the top of the microscope the draw tube having been removed, requires special care. It must move freely up and down in the aperture of the camera box and it should fit *inside* the tube of the microscope and when in position it must be quite light tight. It is made of zinc or card as shown in the illustration (Fig 2) and is fixed on the upper side of the floor of the camera box, the flange resting on the floor and over reaching the margin of the aperture in the box cuts off any stray rays of light The special stanchion hinges cause it to move

FIG 1

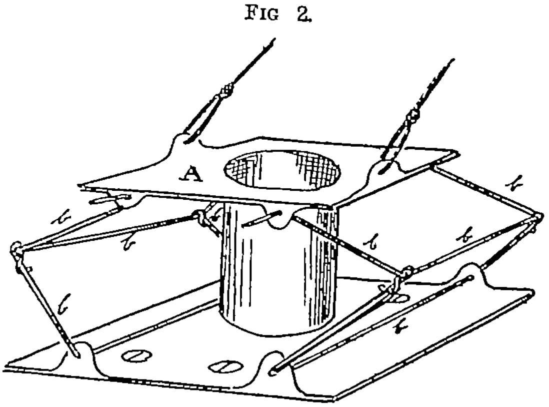
FIG 2.



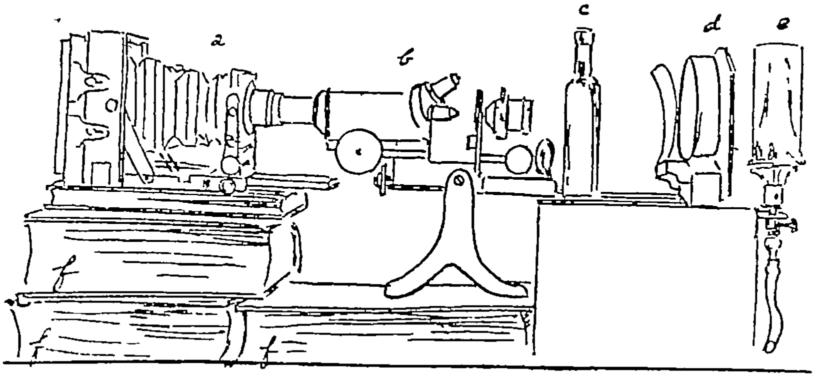
Moveable velvet lined zinc union to connect the camera box with the microscope A Flange attached to the union tube which falls through plate with circular aperture and is fixed to floor of box-camera.

freely and perpendicularly in the aforesaid aperture It can be lifted in an upward direction by means of a string passed through the side of the box at the top, the string being fastened by passing a loop of it over a suitable peg on the outside of the box, so that when released the union tube will fall into position into the tube of the microscope. The union tube should be lined with black velvet to prevent reflection of light. The platform on which the microscope stands should have blocks fastened to mark the exact spot to be occupied by the stand of the microscope, so that it may be immediately under the aperture through which the union tube falls. This also insures exact centering of the image thrown on the quarter plate clear glass screen, fixed at the top of the camera box. On the top of the camera box is fixed the reversing back of a quarter plate camera, but the ground glass focussing screen, which is useless in this work, must be removed and replaced by a sheet of thin *clear* glass free from bubbles and scratches. The lamp is placed on the floor and for comfort should be inclosed in a box. A magic-lantern fitted with an incandescent gas burner, with the door at the back opened, answers every requirement in this respect Incandescent gas is most convenient—it is brilliant, steady, and of constant actinic value.

The stains selected in micrography often throw great difficulties in the way of the photographer, rendering it impossible to obtain really good negatives and necessitating the use of light filters of great depth of colour, with a corresponding diminution of actinic light value and an increase in the length of exposure When it is known that a specimen is to be photographed the stain should be specially selected with a view to this if possible Hæmatoxylin is suitable for sections. Gentian violet gives the best results with bacteria. Fuchsin should be avoided. In fact, it can be roughly stated that all stains on the blue or violet side of the spectrum answer best and stains belonging to the red end of the spectrum give the worst results. Golgi preparations give most satisfactory negatives. Sections stained with hæmatoxylin or other blue dyes are very actinic and it is necessary to exaggerate the shadow thrown by them. This is done by colouring the light before it enters the condenser of the microscope with a light filter or colour screen of a tint complementary to the stain In most cases the screen sold by photographic dealers for landscape photography will be found sufficient, this is a light brown yellow glass screen Should the section be thin and the staining slight or faded greater depth of colour will be necessary in the light filter This can be obtained by staining a film of gelatin on a glass plate with picric acid, or, better still, by using a glass trough or bottle filled with a solution of bichromate of potassium The light filter, however constructed, must be placed between the light and the microscope. If a coloured glass screen it is fitted into a frame which is hinged to the platform on which the microscope stands so that it can be raised or lowered at discretion. To this frame is also hinged a sheet of vulcanite, in order to cut off all light from the microscope when manipulating the dark slide before and after making an exposure

If possible, all preparations of a series to be photographed should be stained with the same dye, as this will simplify the calculations necessary to find the time of exposure, will suit one quality of plate and one light filter, and will render

FIG 3



a Photograph camera with single lens b Microscope with eye-piece. c Light filter (flat bottle filled with solution of bichromate of potassium) d Condenser of magic-lantern. e Incandescent gas burner f Books used to equalise levels of the instruments to that of the gas burner sible an exact comparison of the various results and a rect relation of their several details. Apochromatic ectives should always be used. Achromatic objectives e a blurred image, as the visual and actinic foci are not ncident. The objective of the microscope should be ished and care should be taken that no dust has umulated on the upper surface of the lens The Abbé idenser must be carefully centred before each exposure. is is most important. The specimen to be photographed ring been placed on the stage of the microscope and ussed, the best possible definition d illumination are obtained by ving the Abbé condenser to and . The *eye-piece*, which increases amplification but mars the de ition when this method is used, d the *draw-tube*, which reduces area of the illuminated field, now *removed*. The microscope now placed on the platform in proper position already marked der the camera box. The velvet-ed union is lowered and adjusted. ie lamp is placed in position and e light filter is interposed between mp and Abbé condenser The iage now thrown on the plain ass focussing screen by the micro-ope can with the aid of a com-iund focusser be sought for To id this image, gently turn the cussing screw of the microscope so to increase the distance between e objective and the cover glass of e preparation. Only a small portion the specimen can be focussed at ie time The most important features of the preparation iould be clearly defined and the surrounding field of the jecimen disregarded. The specimen outside the focal lane, though histologically indistinct, will nevertheless give good image photographically When the focus that shows he desired detail with the greatest clearness possible is btained the vulcanite shutter is closed, the dark slide is laced in position, and the plate is exposed in the usual vay

The time of exposure depends on so many circumstances hat it is impossible to give any but approximately correct lirections. When incandescent gas is employed and a andscape light filter of a density increasing exposure three-old is made use of the following table will be found ipproximately correct —

1 inch objective magnifying	25 diameters	... ..	10 minutes
½	50		25
¼	120	...	60
1/12	260		2½ hours

These dimensions it must be remembered, result when the objective alone is used. Two or three times the above exposures will do no harm, as it is almost impossible to over-expose in photomicrography Backed chromatic plates should always be used, they will be found suitable for all blue- and red stained specimens.

It is assumed that the reader is familiar with the photographic processes generally employed for making negatives lantern slides, and paper prints It will therefore not be necessary to enter fully into the details of development. A developer that will produce dense, clear negatives should be used. The following formulæ will be found suitable —

I	Sulphite of sodium ..	3 ounces
	Hydroquinone	½ ounce
	Bromide of potassium	¼ ounce.
	Distilled water ...	25 ounces.
II	Carbonate of sodium	6 ounces.
	Distilled water	25 ounces

Mix equal parts of these two solutions. Development should not be stopped till the disc on the plate is quite black when examined by transmitted light and held about three inches from the dark room lamp, and the image should show quite clearly at the back of the film through the glass by reflected light Under-exposure gives grey weak negatives, often full of detail but too thin to print. In such a case make a transparency on a chloride of silver lantern plate (Alpha) Intensify this transparency with uranium and make from the intensified transparency a new negative on a bromide of silver lantern plate (black tone) Mercury should not be used for intensification, as the results are uncertain and the details in the shadows are liable to be clogged. By this means a quick printing negative of good colour is obtained without risking the original

To determine the amplification given by each objective in this camera a photograph of a micrometer scale should be taken All photographs made with the same objective in the camera will be on exactly the same scale as the negative thus produced, which will be found invaluable for measurements on negatives lantern slides, and prints.

Fairly satisfactory photographs of microscopic specimens can be obtained without making any special apparatus in the following manner Fit to an ordinary camera a single or landscape lens (a doublet is not suitable) and replace the ground glass focussing screen with a sheet of *clear* glass as previously described. Use a compensated *eye-piece* with the microscope and focus in the usual manner Remove the light mirror from the microscope, place it in a horizontal

Fig 5

Taken with photographic camera without microscope (Fig 4) *a* With wooden extension. *b* Without extension.

position with the lamp and light filter in front of it, and adjust the camera with the lens of the camera touching the eye piece of the microscope (Fig 3.) Look with the naked eye into the clear glass screen to ascertain that the apparatus is in a straight line. The camera should be racked out so that the photographic lens is placed at its own solar focal length from the focussing screen This can be done with sufficient accuracy by focussing the image projected by the microscope. Move out the Abbé condenser to obtain even illumination Looking through the compound focusser, carefully focus the image, using first the focussing screw of the camera and then the focussing screw of the microscope. The focus and position of the Abbé condenser will also affect the focus of the image on the screen. This is vitally important and therefore must not be forgotten The Abbé condenser should be moved to and fro till its correct position is found. Actually, the further the condenser is from the stage of the microscope the better is the definition, but care must be taken not to reduce unduly the illumination Expose and develop the plate as previously described. The time of exposure will be about the same for each objective as when using the special camera—i.e, when the ocular and draw tube of the microscope are not used The lens of the camera must be exactly adjusted to the eye piece of the microscope and the instruments arranged in a right optical line, they must be brought to the same level by building a stage with books or other convenient material in order that the illuminated field may not be irregularly curtailed. The amplification depends on the focal length of the lens of the camera, therefore the position of the camera will not alter the size of the image, but the diameter of the illuminated field diminishes very rapidly as the distance between the eye piece of the microscope and the lens of the camera is increased, and *vice versâ*.

It is sometimes desirable to make a photograph showing the whole of a section, which may measure half an inch in diameter This is obviously impossible if a microscope be used, but such a photograph can readily be obtained by using an ordinary photographic camera with a wooden extension increasing the distance between the lens and the focussing screen. (Fig 4) A good wide angle photographic lens of short focus is attached to the camera. A carrier of cardboard or wood, blackened inside, is constructed to hold the section in front of the lens This carrier is made on the principle of the old fashioned photographic box cameras, and consists of two boxes, one sliding inside the other, thus enabling the photographer to vary the distance at which the section is placed in front of the lens, and at the same time preventing any rays of light entering the lens except directly through the section An ordinary camera when extended to its utmost length is usually too short for this work, producing an image of about the same size as the original section. To obtain a larger image the distance between the lens and the focussing screen must be increased. A wooden extension shaped at one end to fit the back of the camera, and with the reversing back of the camera fitted to the other end, will effect this The extension must of course be blackened inside to prevent reflection of light

When using a photographic lens of five inch focal length, with the specimen seven inches from the diaphragm of the lens, an image will be in focus at 19 inches from the lens and the enlargement will be threefold By placing the section nearer the lens and suitably increasing the length of the extension the image can be enlarged to any desired amplification (Fig 5) The lamp must be placed on the table directly in front of the lens and object carrier, a sheet of fine ground glass and a suitable light filter being interposed between the lamp and the section in order to diffuse and to correct the light according to the colour stain of the section. The image is focussed on the clear glass screen by altering the position of the section and by using the focussing screw of the camera. Exposure and development of the plate require no modification

In giving these directions, which are based upon personal experience and the verification of all the points emphasised, I have been as pointed and laconic as possible in language, using the imperative mood notwithstanding its inelegance, in order that my meaning might be as clear as possible, and especially for the instruction of those who have had little or no practical experience in photomicrography I have appended drawings and photographs to illustrate the various methods discussed

Gloucester terrace W

A CASE OF HERNIA INTO THE FOSSA DUODENO JEJUNALIS

By CHARLES T ANDREW, B Sc., M.B, Ch.B Aberd,
JUNIOR DEMONSTRATOR OF ANATOMY ABERDEEN UNIVERSITY

THIS rare form of hernia was found in an old male subject in the dissecting room. When the abdominal wall was opened by a crucial incision in the course of dissection it was noticed that no small intestine was visible when the great omentum was thrown upwards, also that there was a large empty cavity in the pelvis between the sacrum and the bladder As the parietal peritoneum was reflected on to the fundus of the bladder one and a half inches above the symphysis pubis I thought at first that the space was due to the fact that the bladder prior to hardening in formalin had been greatly dilated and so pushed the small intestine out of the pelvic cavity There appeared also to be a large empty space under the left dome of the diaphragm of such dimensions that the closed fist could with ease be slipped under the costal margin, a thing which cannot be done when the subject has been hardened by formalin. In this space the whole of the gastric surface and anterior border of the spleen could be seen from the outside without first drawing the stomach to the left. The whole of the small intestine, with the exception of the lower six inches of ileum, lay in a large sac of peritoneum which ran across the abdomen, lying in the epigastric, umbilical, left hypochondriac, and left lumbar regions To the left the sac extended to the extreme left of the abdomen, to the right as far as the margin of the right rectus muscle. Situated one inch above the bifurcation of the abdominal aorta and slightly to the left of the mid line there was found a distinct semilunar shaped opening looking downwards and to the right towards the cæcum, from which it was distant about two inches The free margin of this ring was thickened and fibrous and stood out very distinctly as it arched over the entering bowel. At the left margin the inferior mesenteric artery came off the aorta and the left colic branch ran forward and upward in the left cornu of the opening The right cornu, with the continuation of the left colic artery, arched over the bowel and then ran upward for a distance of three and three quarter inches to end at the duodeno-jejunal flexure opposite the second lumbar vertebra

It so appeared that the opening of the peritoneal sac was displaced by the weight of the contents from the second to the fourth lumbar vertebra The inferior mesenteric vein lay immediately to the left of the opening The whole of the small gut with the exception of the lower six inches lay in a large hernial sac formed originally by the fossa duodeno-jejunalis described by Treves and situated at the commencement of the jejunum This fossa, the orifice of which looked upwards and to the left and formed by a delicate fold of peritoneum passing from the beginning of the jejunum to the under surface of the transverse meso colon, was found in five out of ten subjects

The size of the fossa is such that, as a rule, it scarcely admits the tip of the little finger In four of the cases in which it was present the margin of the orifice was thin and delicate, but in one old female subject the opening was bounded by a distinct ring, as in the case described, which ended over the duodeno-jejunal flexure, the left cornu formed by the left colic artery which ran in the margin and the right by the commencement of the mesentery

In this case a fold of peritoneum passed from the duodeno-jejunal junction to the under surface of the transverse meso-colon, bounding a fossa which looked to the right but evidently quite apart from the fossa into which the commencement of the jejunum would slip at the first stage of the formation of the hernia, when the top of the jejunum slips into the fossa and is followed from above downwards by the rest of the small intestine As the folds of peritoneum in this region passing from the jejunum to the transverse meso-colon are very variable and as it is necessary in the formation of this kind of hernia that the orifice of the sac should be distinct I propose to name the ring which I have described the "annulus colicus sinister" as the left colic artery runs in its margin The large intestine was greatly distended and the transverse lon crossed the hernial sac near its lower margin, being arkedly narrowed for a distance of four inches to the left the mid line. The descending colon was thrown into a ge sigmoid loop which occupied all the abdominal cavity the right of the rectus muscle and flattened out the all bladder against the under surface of the right be of the liver. There were old peritoneal adhesions etween the gall-bladder and the hepatic flexure of e colon. The liver appeared to have been thrown ack by the pressure of the colon, the lower margin rossing the sternum at the seventh costo-sternal junction, nd the gall bladder was situated opposite the eighth rib in he anterior axillary line. The under surface of the right obe was deeply indented by the hepatic flexure of the colon. he transverse colon crossed the abdomen from the tip of he ninth right costal cartilage to the left anterior superior pine situated six and a quarter inches behind the tip of the iphoid cartilage. Unfortunately during manipulation the ac was torn slightly so that an attempt at reduction without first incising the wall was impossible, but as it stood eduction of the whole of the contents was easy, the bowels eing empty and collapsed but showing no evidence of strangulation.

I am indebted to Professor R. W. Reid and Mr. H. M. W. Gray for kind assistance in making these observations.

Aberdeen.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SHORT NOTE ON THE CURE OF TRACHOMA BY X RAY TUBE EXPOSURE AND BY HIGH-FREQUENCY BRUSH DISCHARGES.

BY SYDNEY STEPHENSON, C.M. EDIN.,

AND

DAVID WALSH, M.D. EDIN.

TRACHOMA, or "granular lids," as is well known, is a formidable and obstinate contagious malady that even in the most experienced hands, can rarely be cured within one or two years. Any remedy therefore, that shortens the period of treatment to weeks must claim widespread and earnest attention. We believe that such a curative agent exists in two forms of electrical discharge—first, that given off by the x ray focus tube and secondly the brush discharge obtained from a d'Arsonval high frequency apparatus. One case of the treatment of trachoma by focus tube exposure has been reported by Mr. M. S. Mayou.[1] We have treated a single eye in four cases of severe bilateral trachoma in children. Two eyes were cured—that is to say, the granulations and conjunctival hypertrophy disappeared and have not returned after a period of several months. The remaining two eyes were greatly benefited and were well on the road to ultimate cure. The cures were effected by 17 exposures in the one case and by six in the other, with an average exposure of 10 minutes and a distance of about eight inches of the antikathode from the lid. The good effects were found to be equally marked with closed as with everted eyelids. 22 applications of a mild high-frequency brush applied by means of a vulcanite electrode connected with a d'Arsonval apparatus cured a severe case of trachoma in another patient.

The radiotherapy of trachoma presents several obvious advantages over the ordinary treatment by escharotics—as, for example, its painlessness, its great rapidity and its simplicity. The fact that a severe malady like trachoma (which has led to the expenditure of many thousands of pounds of public money in this country alone) can be cured by exposure to an active focus tube and to a high frequency brush suggests that the curative agency may be identical in both instances. This observation may possibly throw fresh light on the therapeutic action of the focus tube, a point about which little is really known. The common agency may be a brush discharge, visible from the high frequency electrode and invisible from the focus tube. In any case the introduction of new and powerful methods of treating trachoma must have an important bearing upon the victims of ophthalmia in many countries.

ARTHRITIS AS A COMPLICATION OF MEASLES.

BY ROBERT CRAIK, M.D. GLASG.

A HEALTHY boy, aged seven years, suffered from whooping-cough in June, 1902, which lasted for two or three months but did not seem much to impair his health. He had been quite well for over a month when he complained of pain in his left knee on Nov. 2nd. On the 1st he had been quite well and had helped to gather sticks for a bonfire on the 5th. His mother thought that he had hurt his knee in getting sticks from the hedge-roots. But he always maintained that he had not hurt himself, so that any injury he sustained must have been trifling. There was no sign of any scratch or bruise or of any swelling but the lad limped a little. On the 3rd as he complained less he was sent to school but as he limped home at mid-day he was not allowed to go back. On the 4th and 5th he sat about the house looking out of sorts and occasionally complaining of his left knee. On the morning of the 6th he was covered with the rash of measles and he remained in bed all day. He was first seen on the 7th when he appeared to have a typical attack of measles, an epidemic of which prevailed at the time. He had slept well during the preceding night and was resting comfortably in bed. Nothing was said about the knee. On the 8th, however, the mother mentioned the matter and I found there was pain about the joint on pressure and on movement. The boy did not care to move the left leg at all, but lay on his left side with the joint flexed, in which position alone he seemed comfortable. There was little or no swelling or redness, but I suspected there was some effusion into the synovial cavity. The patient was feverish on the 7th but on the 8th the temperature was normal when I visited him. The knee was covered with cotton wool and a bandage was applied. It seemed easier for a few days, but movement was always painful and there was soon distinct evidence of effusion. The effusion increased and at my daily visits the temperature varied from normal to 99° or 100° F. On the 30th the effusion was very great and there was a faint blush on the inner aspect of the joint above the patella. The joint was opened freely on each side of the patella. A large quantity of synovial fluid escaped and a little pus which seemed to come from the interior of the joint was evacuated on pressure. After washing out the synovial cavity a drainage-tube was passed under the patella and out at the opposite side and left in for several days. Recovery appears to be quite satisfactory and the little stiffness will probably soon disappear.

This is an example of arthritis following so soon after measles as to suggest that the measles caused the joint affection. A history of injury often precedes pneumococcic arthritis, and the injury probably determines the attack. There is no mention of arthritis as a complication of measles in most of the text-books, certainly none in Osler's "Text-book of Medicine," in Allbutt's "System," or in Watson Cheyne's "Manual of Surgery." Rose and Carless say that arthritis sometimes attacks children *after* measles. Had it been scarlet fever instead of measles the arthritis would certainly have been attributed to the scarlet fever.

PATHOLOGICAL SOCIETY OF LONDON.

A Higher Mould Fungus isolated from a Case of Multiple Granulomatous Tumours.—The Resisting Powers of Staphylococcus Pyogenes Aureus against the Persalts of Mercury.—A Diphtheroid Bacillus isolated from Two Cases of Puerperal Fever.—A New Pathogenic Diphtheroid Bacillus.—The Morphology and Distribution of Bacillus Pestis and some Similar Microbes.

A MEETING of this society was held on Jan. 20th, Dr. E. KLEIN, the Vice-President, being in the chair.

Dr. W. S. LAZARUS-BARLOW made a communication on a Higher Mould Fungus that he had isolated from a case of Multiple Granulomatous Tumours. The patient, a man aged 42 years, showed a number of raised and reddened masses on an area of the back approximately a foot square at the point of the greatest agglomeration of the masses, but actually more or less covering the back and flanks between the scapulæ and the crests of the ilia. Many of the foci were as large as walnuts. From first to last when the patient was discharged improved he was under observation about two years. It was at first thought that the condition was syphilitic, but subsequently, after anti syphilitic treatment had proved ineffectual, the provisional diagnosis was actinomycosis By this time the masses had begun to show central softening and were opened with full antiseptic precautions The pus so obtained was caught in a sterile test-tube On examination it was found to contain a small number of spherical grains similar to those present in the pus of actinomycosis Tubes of maltose broth were inoculated with the pus and a mould was obtained as the only growth In portions of tissue removed at the same time from the man s back foci of a mycelium were found that stained by Gram's method and conformed satisfactorily with the growth obtained from the pus. Subsequent attempts to cultivate the organism from the pus discharged from the opened abscesses failed, only streptococci and staphylococci being obtained The mould grew on all the ordinary media, but most satisfactorily upon those made with maltose and on potato It was aerobic, grew better at 37° C than at the room temperature, did not grow on gelatin, did not coagulate milk, formed acid, had a very slight diastasic action on starch, formed flocculent balls in liquid media leaving the medium itself clear, and on solid media appeared first of all as a white, filmy mycelium that grew superficially and into the depth, and subsequently became either waxy in appearance on the surface or covered with a velvety layer of coffee colour In all cases the ultimate condition was of the last-mentioned kind Aerial hyphæ were formed. The organism stained with the ordinary anilin colours as well as by Gram's method, and it was neither acid- nor alcohol fast. The mycelium was branched and dichotomy was common though not invariable In old cultures it was seen that the mycelial filaments broke up into chains of spores resembling those occurring in the streptothriceæ in arrangement but oval in shape and much larger In spite of the general resemblance to the streptothriceæ in mode of growth it differed essentially in the far greater size of the hyphæ and of the spores The organism did not appear to have a special form of fructification for its spores Dr Lazarus Barlow had been unable to identify the mould —Mr A. G R. **FOULERTON** said that the artificial cultures resembled sporothrix, though the sections of the tumour itself did not do so Clinically, the case also resembled those examples of sporothrix infection which had been described, for the tumours were multiple and had a tendency to break down

---

[1] Transactions of the Ophthalmological Society, vol. xxii. 1902.

Dr F W **ANDREWES** brought forward facts relating to the Resisting Powers of Staphylococcus Pyogenes Aureus against the Persalts of Mercury It was well recognised that this was one of the most resistant non sporing organisms both against heat and chemical disinfectants, but it was not sufficiently recognised that its resistance against mercuric salts was altogether exceptional. This fact was of special importance in surgical disinfection. Dr Andrewes described observations which he had made on a strain of this coccus which appeared to possess unusual powers of resistance and which in broth cultures resisted 1 in 500 perchloride of mercury for 45 minutes, and in pure water for 12½ minutes By repeated passages through the disinfectant, in which it might be supposed that only the most resistant survived, transmitting their resistance to their progeny, a strain of staphylococci was produced which had even higher powers of resistance. The results finally obtained were as follows. The cocci resisted 1 in 500 perchloride of mercury in pure water for 20 minutes, 1 in 1000 perchloride of mercury in pure water for 50 minutes, 1 in 1000 perchloride of mercury in 0 3 per cent. salt solution for 80 minutes and 1 in 1000 perchloride of mercury in nutrient peptone-broth for over four hours. The resistance against biniodide of mercury was equally great, but it did not in the least extend to antiseptics of other groups. Carbolic acid, 1 in 40 killed the cocci in less than two minutes, and 1 in 400 medical izal in less than one minute. These results might be exceptional, but in routine disinfection it was necessary to provide against the exceptional as well as against the commonplace.—Dr F J **POYNTON** asked if Dr Andrewes had made similar observations with regard to the cyanide of mercury —Mr **BISHOP HARMAN** said that in recent experiments which he had made on the staphylococcus pyogenes aureus and t coccus he had isolated from the South African veldt sore ascertain the relative resistance of these organisms perchloride of mercury, amongst other methods he had us that of very free dilution of the cultures with a lar quantity of the antiseptic—viz, 1 cubic centimetre of broth culture mixed with 49 cubic centimetres of t antiseptic to equal 1 in 1000 perchloride of mercur In these conditions the staphylococcus pyogenes aure had survived 20 minutes' exposure and the veldt sore cocc 40 minutes, beyond which he had not gone. He furth noted a great increase of stickiness of the colonies due t the production of a glutinous "capsule" which he thoug might act as a protective It appeared that Abbot had note this feature in 1891, further Abbot had taken extr ordinary precautions in his experiments to prevent clumps o organisms being exposed to the antiseptic, in which co dition he supposed them to afford each other some protectio from the action of the reagent —Dr **KLEIN** asked if D Andrewes had compared the strain of staphylococcus wit which he had experimented with ordinary laboratory culture of the organism and suggested that the strain with whic he had experimented might be especially resistant.—D **ANDREWES**, in reply, said that he had not made an observations with the cyanide of mercury He had no during his experiments noticed any increased stickiness o the colonies after treatment with perchloride of mercury

Mr **FOULERTON** and Dr W F **VICTOR BONNEY** communicated a paper on a Diphtheroid Organism Isolated from the Uterus in two cases of Puerperal Fever. This organism, which in morphological and cultural characteristics closely resembled the bacillus diphtheriæ, was isolated in pure culture from the cavity of the uterus of a woman o the seventh day after a normal confinement, and from the upper part of the cervical canal of a woman in whom, 1 days previously, a miscarriage at the end of the second month had occurred In both cases there was considerable pyrexia and in both the patient recovered—in the second case, however, after a prolonged illness. The bacillu was, perhaps, a little larger and coarser than bacillus diphtheriæ, but presented the same variation of morpholog characteristic of the latter organism. On nutrient agar cultures, after 24 hours' incubation at 37° C, long, beaded, spindle shaped, pear shaped, Indian club-shaped, and coccal forms might be seen. In broth cultures the organism appeared chiefly as a rather short evenly staining rod, but even in this medium other forms were occasionally seen. The bacillus stained by Gram's method and was not pathogenic for guinea pigs and the other animals on which it was tested. Whilst the bacillus belonged to the so-called "diphtheroid" group of organisms, it was to be easily distinguished from the bacillus diphtheriæ by (1) the somewhat coarser shape, (2) by the fact that no appreciable amount of acid was produced in glucose peptone broth cultures after six days' incubation at 37° C, and (3) by the fact that it was non-pathogenic for the guinea pig Mr Foulerton and Dr Bonney had met with a similar organism once in a case of catarrh of the cervical canal, and had also isolated a similar culture from a case of phagedæna of the penis, they also thought that it might be allied to the "diphtheroid" organisms which had been described in cases of noma vulvæ and which they themselves had found in cases of cancrum oris There was no direct proof that the bacillus was pathogenic in the cases of puerperal fever from which they had isolated it, but they thought that on the whole there was a strong probability that its presence in the uterus was the cause of the symptoms —Dr G **LESLIE EASTES** said that he had found in the pus from a case of urethritis of a man an organism which closely resembled that described It did not, however, stain well by Neisser's method and was not pathogenic to animals —Mr K. W **GOADBY** said that he had found an almost similar organism in pyorrhœa about the gums. It was not acid fast and did not stain by Neisser's method.—Mr **HARMAN** said that he had found a similar organism in the conjunctival sac in a case of ophthalmia neonatorum The organism was not pathogenic to animals.—Mr **FOULERTON**, in reply, said that because these growths resembled one another there was no reason for regarding them as the same With regard to their occurrence in cases of urethritis he said that he had examined 56 cases of that disease and had never come across a diphtheroid bacillus The point of interest in the present paper was that a definite organism had been found in two definite cases of puerperal fever.

Dr **KLEIN** described a new Pathogenic Microbe belonging the group of Diphtheroid Bacilli It was found in white ts, causing in these animals extensive consolidation of the ngs. In the hepatised parts the alveoli and infundibula nd bronchi were filled with, and distended by, fibrinous xudation, red and white blood corpuscles and continuous asses of the above microbe. Microscopic specimens and antern slides of the microbe as it occurred in the lungs nd under cultivation were shown. The morphological including positive Neisser's test) and cultural characters including acid production) of the microbe appeared identical with those of the bacillus diphtheriæ. Small or large doses f culture caused on inoculation into rodents a firm tumour which gradually enlarged to considerable size and in the ourse of about a fortnight led to the formation of an abscess. This ultimately opened spontaneously and led to complete ecovery No fatal issue in rats or guinea pigs had been roduced by even large doses of the culture Diphtheria ntitoxin, 400 or even 600 units per half grown guinea pig, ad no power to neutralise the pathogenic action of a small ose of the culture.

Dr KLEIN exhibited lantern sides illustrating some points n the Morphology and Distribution of the Bacillus Pestis nd some Similar Microbe.

OBSTETRICAL SOCIETY OF LONDON

Discussion on Puerperal Insanity

A MEETING of this society was held on Jan. 7th, Dr PETER HORROCKS, the President, being in the chair.

Dr ROBERT JONES opened a discussion on Puerperal Insanity His paper was based upon a personal experience of 259 cases of puerperal insanity divided into 120 cases commencing during the actual puerperal period, 83 during lactation, and 56 during pregnancy Insanity was stated to occur once in every 700 confinements It was stated to be of a characteristic form after confinement, amounting to an almost nosological entity, but this was not the case during pregnancy or during lactation, there being no definite type of insanity occurring in connexion with these two stages. The divisions were, however, more convenient than typical. The following propositions were advanced by Dr Jones —1. The insanity of pregnancy was more common in first confinements among single women, the disappointment, shame, and disgrace of illegitimacy being an important factor in the mental breakdown. 2. During pregnancy the mental condition was more often acute melancholia than acute mania and suicidal symptoms, which occurred in 41 per cent., had to be carefully guarded against 3. The insanity of pregnancy was divided into that occurring during the early months and that occurring during the later months, and in these the nearer the insanity in point of time to the confinement the more acute were the mental symptoms. Insanity was not more frequent when the sex of the child was male. 4 The insanity of the puerperium came on after the first confinement in 33 *per cent.* of the cases and supervened suddenly rather than gradually 5. The cases which occurred during lactation presented characters of marked general physical exhaustion and mentally were more often of the depressed than of the maniacal form Lactation insanity became chronic oftener than the insanity of the other periods. There was a tendency to low forms of inflammation, thrombosis gangrene, and phthisis during the insanity of lactation Both suicidal and infanticidal promptings were more common in lactation than in puerperal cases—that was, in cases where insanity commenced more than six weeks after confinement. 6. The early symptoms of threatening insanity were loss of sleep and headache, and these should be a forewarning of mental breakdown. The busy delirium of hallucinatory type ending in acute restless, purposeless mania with religious and erotic delusions, was characteristic of this variety 7 As regards etiology, heredity was more marked and in the direct maternal line in puerperal and lactational insanity and was equally paternal and maternal in the insanity of pregnancy A previous record of hysteria was frequent in puerperal insanity The question of marriage of hysterical persons was considered. 8. The pathology was that of heredity and stress. Was the stress due to a toxin? 9 As regarded prognosis, cases of insanity during early pregnancy improved towards the end of pregnancy whereas those of late pregnancy became worse at the puerperium Puerperal insanity was markedly recoverable. Improvement was rapid being often complete in three months, but generally took from four to five months. 10 With regard to treatment, all cases presenting headache and sleeplessness must have absolute quiet and rest, and sleep must be procured. Home treatment was desirable in all cases if possible. Unusual and sudden impulses of suicide and infanticide must be guarded against The presence of the husband aggravated the symptoms. There was much necessity for a liberal and stimulating dietary Change was necessary in puerperal insanity when cases tended to become stuporous. Menstruation was a sign of mental improvement. Purgatives and iron were well borne. The following special questions were put forward by way of criticism. 1 Was there such a disease as puerperal insanity—a mental alienation which was either caused by the puerperium or an accompaniment of this physiological crisis? 2 If there was, were the mental conditions due to toxæmia or to septicæmia or to both? Or was the delirious mania which occurred in connexion with this period due to extraordinarily emotional disturbances? How far did the moral factor enter into the etiology, and how far did pregnancy in the unmarried state influence the causation of insanity? 3 What was the relation between mania and melancholia? 4 What was the essential pathology of this disease? 5. What was the relation between albuminuria and pregnancy? also between albuminuria and the puerperal state? 6. In Dr Jones's cases, so far as the history could be obtained from the relatives or those present no prodromata of insanity beyond sleeplessness and headache were as a rule noticed and the onset of insanity was sudden, what was the nature of the onset in the practice of obstetric physicians? 7 As to prevention and treatment, did hysteria in youth manifest itself by insanity in later life at the puerperal or other physiological crisis, and should marriage be discountenanced in these? What views should be generally held as to the marriage of neurotic persons? What were the views as to home and asylum treatment, as to local and general treatment, and, a more especially important point, as to the induction of premature labour?

Sir JOHN WILLIAMS dwelt upon the peculiar condition of the nervous system in pregnancy, parturition, and the puerperal state, and reviewed briefly the pathology of puerperal insanity He strongly deprecated the resort to surgical measures in the treatment of this insanity

Dr. G F BLANDFORD said that beyond question the earliest symptom of approaching mental trouble was loss of sleep, and this should be most closely watched and every precaution taken that the patient should not be disturbed by noises or talking in the room, by the child being brought to be nursed or by the visits of friends. With regard to Dr Jones's question, whether the mental disturbance was due to toxæmia or septicæmia or both, it must be remembered that toxæmia and septicæmia were different things. Septicæmia produced puerperal fever, not puerperal insanity

Dr G E. HERMAN said that the main duty of the general practitioner and the obstetric physician in regard to puerperal insanity was to prevent it. Treatment was mainly in the hands of the alienist. To prevent puerperal insanity the great things were to see that the patient got food and sleep. If sleep was absent he thought that the best hypnotic was alcohol. There were objections to alcohol of which in the present day no one was in danger of losing sight. Every hypnotic, if too much was taken, did harm, but the harm done by alcohol, if taken too freely, was far less and far slower in coming than that done by chloral, bromide, morphia, sulphonal, or any other hypnotic, if taken habitually for long periods. Medical men were not justified in taking upon themselves the responsibility of discountenancing a proposed marriage. The utmost that a medical man should do was to express to those concerned whatever fears he might have as to the result of marriage.

Dr C A MERCIER took exception to the statement that headache was a common prodroma of puerperal insanity The only trustworthy indications, he thought, were sleeplessness and loss of appetite. He did not think that single women who became mothers suffered much emotional stress as a rule. Many of them were already half witted and the insanity of the puerperium was only an exaggeration of their usual state. The rest were for the most part upon a low moral plane. He protested strongly against the suggestion that puerperal mania could be treated satisfactorily at home and maintained that institution treatment was always best.

Dr F H. CHAMPNEYS fully indorsed all that had been said about sleeplessness as the striking symptom of threatening insanity and about the pre-eminent value of alcohol as a sedative in such cases It seemed to him that if mental distress were a factor in producing puerperal insanity its frequency after illegitimate births ought to vary directly with the moral standard It was well known that the moral standard with regard to such matters varied greatly in different countries If the above contention were true the proportion of cases of insanity in single mothers ought to be lowest in immoral and highest in moral countries. As regarded toxæmia and its relation to pregnancy he did not think that the explanation given in the paper would altogether suffice. Effete products were doubtless prevalent after confinement, on the other hand, the sense of physical and mental comfort and relief ordinarily experienced after delivery was proverbial. He did not think that this would be the case if ordinary toxins were the usual cause of insanity after labour

Dr W LLOYD ANDRIEZEN stated that the division into insanity of pregnancy of the puerperium, and of lactation was a conventional and not a nosological classification He concluded from a careful study of statistics that illegitimate pregnancy was twice as frequently followed by mental disorder as legitimate pregnancy He regarded puerperal insanity as comprising three main types of mental disorder—viz, first a collapse delirium following upon parturitions attended with marked exhaustion and hæmorrhage, secondly an acute confusional insanity with hallucinatory delirium (frequently misnamed "mania'), and thirdly, mania or melancholia proper or alternating manio-melancholic insanity

Dr F W MOTT said that among the large number of cases recorded by Dr Jones there was not a single case of gangrene, perhaps, therefore, he might be allowed to relate an instance which he had seen in a woman certified as suffering from puerperal insanity who was admitted into one of the London county asylums. This patient not long after admission developed signs of symmetrical gangrene of the feet The child had been born dead and the woman was suffering from septic endometritis. Her mental condition improved when this was treated.

Dr R PERCY SMITH said that with regard to the early symptoms he thought that next to sleeplessness, restlessness and early confusion of thought were more important than headache. There was no definite form of mental disorder which could be looked upon as absolutely characteristic of puerperal insanity, and cases might be of the delirious, confusional, maniacal, melancholic, stuporous, or delusional type. He had very little personal knowledge of illegitimacy as a cause but called attention to Dr T S Clouston's statement that 75 per cent of the puerperal cases admitted to Morningside Asylum followed illegitimate births Another point in the etiology was that 26 per cent of the cases admitted to Bethlem Hospital had had a previous attack of insanity, either one before marriage or one after marriage, which was not puerperal in origin or a previous puerperal attack He said that alienists constantly found a history of previous "hysteria' in patients admitted to asylums which when carefully inquired into was found in many cases to have been a previous attack of definite mental disorder euphemistically called "hysteria." He was sure that such patients ought not to marry

Dr E W WHITE thought that Dr Jones's proportion of occurring cases was too low, probably 1 in 400 confinements was nearer the mark, for there were many which did not go to the asylum for treatment and of which no records were obtainable. He drew attention to certain of the mental symptoms and to the temperature charts in this disease. The obscene language, erotic tendency, and self abuse were probably of peripheral origin from abnormal uterine conditions, altered lochia &c In nearly all his cases there was an elevation of temperature of from one to two degrees in the evening with a morning fall of a degree or less, lasting from ten days to a fortnight, then a subnormal temperature for several weeks Frequent baths with scented soap were necessary on account of the perverted skin secretion.

Dr W S A GRIFFITH stated that with regard to the insanity of pregnancy there was a group of cases quite distinct in which the main feature was the apprehension of the patient, either real or simulated, that unless the pregnancy was terminated she would become insane, he looked upon all such cases with the gravest suspicion, not of insanity, but of rather the reverse—namely, as an ingenious method of putting strong pressure on the medical adviser to produce abortion

Dr T SEYMOUR TUKE agreed with previous speakers in the necessity for good feeding and urged the early resort to artificial feeding if called for While admitting the great value of alcohol the danger of forming a habit must not be lost sight of

Dr T CLAYE SHAW referred to the question of the existence of a mental disorder due to the puerperal state. It appeared to him that there were two classes of cases really existent, but both characterised by the delusions, incoherence, and other mental symptoms supposed to be pathognomonic of insanity due to the puerperal state alone. Insanity characterised by prominence of sexual mental demonstration might occur in young women at the developmental epoch or in women of middle or advanced age in whom there were no uterine or ovarian complications of any kind to be passed through, just as delusions of a sexual character might be seen in boys and men accompanied by acts of masturbation, and yet there was no occasion to attribute the symptoms to influence from the genital organs at the moment. When, however, the temperature was higher than was usually met with in acute insanity and the symptoms came on shortly after parturition, there was a strong argument in favour of a direct connexion between the mental and bodily states, especially when there was a history of hereditary taint, together with the probability of the presence of a septic condition.

Dr J M. AMAND ROUTH urged the desirability of having intermediate receiving houses, or a nursing home, where women suffering from such temporary insanities as those under discussion could be received and treated Such a plan would avoid the stigma of having been in an asylum and would make it much easier to get the friends of the patient to agree to her removal.

The PRESIDENT thought that obstetricians saw these cases, as a rule, at a much earlier stage than did the alienists. Perhaps for this reason, and because of the shortness of time, the introducer of the subject had said but little about diagnosis When the patient was admitted into an asylum the diagnosis had been made, but in the earlier stages it was not always easy to say that a case amounted to actual insanity He considered that the refusal of food was a far graver symptom and pointed much more certainly to insanity than did sleeplessness

Dr JONES replied briefly

LARYNGOLOGICAL SOCIETY OF LONDON—A meeting of this society was held on Jan 9th, Mr E Cresswell Baber, the President, being in the chair—The following officers were appointed for the year—President Dr P McBride. Vice-Presidents Mr A A. Bowlby, Dr Dundas Grant, Dr P Kidd, and Mr C J Symonds. Treasurer Mr. W R H Stewart. Librarian Dr StClair Thomson. Secretaries Dr J Donelan and Dr E. Furniss Potter Members of the Council Sir Felix Semon, Mr E Cresswell Baber, Mr C A. Parker, Dr W Permewan, Mr R. Lake, and Mr L A. Lawrence.—Sir Felix Semon exhibited a case (which had been previously shown at the November meeting of the society) of Ulceration of the Left Tonsil with Enlargement of Numerous Cervical Glands on both sides of the neck (? malignancy) in a man, aged 70 years It was now seen that the ulceration had disappeared and that the tonsil had become much smaller, whilst the enlargement of the cervical glands had considerably diminished Malignancy was now excluded. The case was shown again as affording valuable evidence that ulceration of a tonsil in old people with enlarged glands must not necessarily be looked upon as malignant—Dr P Watson Williams exhibited new designs for Sphenoidal Sinus Cutting Forceps and a Laryngeal Spray—Dr A. Bronner showed a drawing and read notes of a case of Suppurative Ethmoiditis and Frontal Sinusitis after radical operation for Nasal Polypi. The nose had been curetted on three occasions with Meyer's ring knife Four weeks after the last operation the patient began to have pain, a high temperature, and became semi comatose. The nose and forehead became swollen. Both frontal sinuses were opened and found to be full of pus The dura mater was exposed. The patient was relieved for 12 hours after the operation and then died. The anterior part of the left frontal lobe was found to be necrosed and there was extensive purulent basal meningitis.—Dr H. L Lack showed a man, aged 59 years, with Aphonia of six months' duration who had a similar attack ast year He spoke as if the glottis were closed but could sing with a natural voice —Dr McBride was of opinion that this case was one of spastic aphonia.—Dr Lack also showed a microscopic section from a Large Ulcer of the Tonsil in a woman, aged 25 years, showing (?) tubercles There was no history of syphilis but the case yielded immediately to iodide of potassium.—Dr Lack also showed a Microscopic Section of a Cyst of the Ventricle of the Larynx opened when operating on a case of malignant disease of the larynx.—Mr Lake exhibited specimens of New Growths removed from the Nose (1) of the Posterior Extremity in a male aged 52 years, (2) of the Septum and Inferior Turbinal in a male, aged 28 years, and (3) of the Inferior Turbinal in a patient, aged 72 years (an old lupus case) —Dr H. Tilley showed a case of Large Hypertrophy of the Mucous Membrane in the Arytenoid Region (so-called inter arytenoid pachydermia) in a robust-looking man, aged 48 years.—Dr. Donelan showed a specimen of a Large Naso-Pharyngeal Fibro Myxoma with prolongations extending to the anterior nares in a youth, aged 18 years —Dr Barclay Baron showed a case of Naso-Pharyngeal Malignant Disease in a woman, aged 50 years. The patient had complained of deafness and nasal obstruction and discharge of blood and pus from the nose for about eight months. Three months previously a hard, irregular growth had been removed by scraping from the naso-pharynx with relief of all the symptoms. The *symptoms had again returned and the* naso-pharynx was filled with growths which protruded into the nostrils The nature of the growth was uncertain, in places it had the appearance of lympho-sarcoma.—The President, Mr. W G Spencer, Dr McBride, Dr W Hill, and Dr Pegler discussed the case.—Mr Atwood Thorne showed a case of Epithelioma of the Larynx in a man, aged 60 years. There had been hoarseness for six months previously, the left cord was seen to be fixed in the middle line and a growth was observed involving the left arytenoid and ary-epiglottic fold. There were slight tenderness to external pressure and a large gland under the ramus of the jaw on *the left side. There was no history* of syphilis Potassium iodide had been given for the last fortnight, but without any appreciable benefit The case was discussed by the President, Dr Lack, Sir Felix Semon, Mr Waggett, Dr Dundas Grant, and Dr McBride. The opinion expressed was that the case was not suitable for operation.—Dr Fitzgerald Powell showed (1) a case of Infiltration of the *Pharynx and Post-nasal* Space in a man, aged 45 years, probably syphilitic, and (2) a Growth in the Post-nasal Space appearing below the soft *palate in an infant, aged* 18 months, for diagnosis.—Mr Spencer showed a case of Symmetrical Swellings of the Gum at the posterior extemity of the alveolar border of each upper jaw in a woman, aged 37 years.—Dr W H. Kelson showed (1) a woman shown at a previous meeting suffering from Aphonia due to a rounded growth originating in the left ventricle of the larynx which had been removed, and on examination under the microscope was found to be a fibroma undergoing mucoid degeneration, and (2) a case of Recurrent Fibrous Polypus of the Nose in a man, aged 26 years.—Dr Dundas Grant showed a case of Chronic Laryngitis with Inter arytenoid Pseudo-pachydermic Swelling probably due to purulent rhinitis in which the hoarseness had much diminished and the inter arytenoid swelling had become smaller during the use of a nasal wash for one week.—Dr Dundas Grant also showed a case of Hereditary Specific Perforation of the Left Anterior Pillar of the Fauces

DERMATOLOGICAL SOCIETY OF LONDON —A meeting of this society was held on Jan 14th, Dr H Radcliffe Crocker being in the chair —Dr Radcliffe Crocker showed a middle aged man who for nine weeks had been affected by the appearance of reddish pink, oval, slightly elevated, and slightly desquamating Patches on both Flanks and on the Left Arm The patches were about three inches long by two inches broad and their long axes lay in the direction of the lines of fissure of the skin. They had been apparently somewhat benefited by treatment and the reason for showing the case was to ascertain the opinion of the members as to whether it was probably an early stage of mycosis fungoides or not.—Most of the members thought that the evidence was not sufficient to lead them to suspect mycosis fungoides —Dr J H. Sequeira showed a man who had had Lupus Erythematosus of typical appearance affecting the scalp, face, and ears for four years and who for the last year had also suffered from a papulo vesicular and weeping eruption resembling eczema on the arms, buttocks, and thighs The question was whether the second eruption was a simple eczema or whether it was *one of those very acute phases* of lupus erythematosus of which examples had been shown to the society —Most members, though admitting the difficulty of making a definite diagnosis without watching the case, were inclined to believe that the disease on the extremities was really eczematous.—Dr A. Whitfield showed a child, aged three years, suffering from Tinea Tonsurans of the microsporon variety treated by x rays The child had had two patches of the disease for many months and one of these had been treated first. In all 14 exposures had been given, with the result that every hair, both sound and diseased, had fallen out entire one week after the cessation, and this patch was cured The hair was beginning to grow again slowly three weeks later The other patch was under treatment and had had ten exposures without any hair falling out. Slight reddening had, however, begun to be visible and Dr Whitfield thought that a very few more exposures would cause shedding as before He pointed out that a little more experience was required before introducing the treatment generally and that it must be carried out carefully as in some cases the hair had apparently not returned, but he thought the method compared favourably with all others in rapidity, cleanliness, and painlessness. It was, of course best adapted for patchy cases —Dr J M H. M'Leod showed a child, aged six years, with a rapidly developing diffuse and areate Alopecia. The whole duration of the disease was three weeks and already most of the hair on the head was lost The scalp was very scurfy and entirely free from oily seborrhœa There was some plugging of the follicles but no micro-organisms had been found either in the scales or hairs. The number of clavate and other forms of atrophied hairs present was very striking

BRISTOL MEDICO-CHIRURGICAL SOCIETY —The *fourth meeting of the session of this society was held* in the medical library of University College on Jan. 14th, Mr G Munro Smith being in the chair —Mr J Paul Bush, C M G, showed a Fibroid Tumour of the Uterus and Papillomatous Cyst of the Ovary removed by operation A fistula of the ureter ensued which healed completely without further surgical interference —Dr E W H Groves, Dr J L. Firth, and Dr W C Swayne remarked on the specimen.—Mr E. H. E Stack showed a most interesting series of Contracted Pelves and pointed out that *it was those cases* where a moderate amount of contraction was present that gave rise to the greatest difficulty, as in extreme cases of contraction the deformity was usually diagnosed at a much earlier period.—Dr Swayne and Mr Munro Smith spoke on the subject —Mr A. W Prichard read notes on a case of Ruptured Intestine successfully operated upon in which there was tuberculous disease of the peritoneum —Mr C A. Morton, Mr Munro Smith, and Mr Bush commented on the case —Dr H. G Kyle read notes of a case of Perforated Typhoid Ulcer that he had operated on in which the perforation could not be efficiently closed with sutures and in which he had placed the perforated intestine beneath the abdominal incision, surrounding it with gauze, the patient eventually died from a continuance of the enteric fever —Dr J O Symes Mr Bush, Mr W H Harsant Mr Stack Dr Groves, and Mr Morton spoke on the subject.—Mr H. F Mole read a paper and showed the specimens of two cases of Ruptured Tubal Pregnancy, in one the rupture had taken place into the general peritoneal cavity and in the other between the layers of the broad ligament.—Mr T Carwardine made some remarks on the paper

SOUTH-WEST LONDON MEDICAL SOCIETY — A meeting of this society was held on Jan 14th, Surgeon Major Mark Robinson, I.M.S., the President, being in the chair —Mr P M Yearsley read a paper on the Indications for the Mastoid Operation. He said that the mastoid operation for the relief of acute suppuration in the adnexa of the middle ear and the *modified* complete radical post-aural operation for the cure of chronic middle-ear discharge had taken an important place in modern surgery The operations originated by Schwartze, Stücke, and Ballance and the complete post-aural operations were briefly explained. These operations belonged to one of two groups (1) the opening of the mastoid antrum without interfering with the middle ear, and (2) the *opening* of the antrum and the formation of one large cavity common to said about sleeplessness as the striking symptom of threatening insanity and about the pre-eminent value of alcohol as a sedative in such cases It seemed to him that if mental distress were a factor in producing puerperal insanity its frequency after illegitimate births ought to vary directly with the moral standard It was well known that the moral standard with regard to such matters varied greatly in different countries If the above contention were true the proportion of cases of insanity in single mothers ought to be lowest in immoral and highest in moral countries. As regarded toxæmia and its relation to pregnancy he did not think that the explanation given in the paper would altogether suffice. Effete products were doubtless prevalent after confinement, on the other hand, the sense of physical and mental comfort and relief ordinarily experienced after delivery was proverbial. He did not think that this would be the case if ordinary toxins were the usual cause of insanity after labour

Dr W Lloyd Andriezen stated that the division into insanity of pregnancy of the puerperium, and of lactation was a conventional and not a nosological classification. He concluded from a careful study of statistics that illegitimate pregnancy was twice as frequently followed by mental disorder as legitimate pregnancy He regarded puerperal insanity as comprising three main types of mental disorder—viz, first a collapse delirium following upon parturitions attended with marked exhaustion and hæmorrhage, secondly, an acute confusional insanity with hallucinatory delirium (frequently misnamed "mania'), and thirdly, mania or melancholia proper or alternating manio-melancholic insanity

Dr F W Mott said that among the large number of cases recorded by Dr Jones there was not a single case of gangrene, perhaps, therefore, he might be allowed to relate an instance which he had seen in a woman certified as suffering from puerperal insanity who was admitted into one of the London county asylums This patient not long after admission developed signs of symmetrical gangrene of the feet The child had been born dead and the woman was suffering from septic endometritis. Her mental condition improved when this was treated

Dr R Percy Smith said that with regard to the early symptoms he thought that next to sleeplessness, restlessness and early confusion of thought were more important than headache. There was no definite form of mental disorder which could be looked upon as absolutely characteristic of puerperal insanity, and cases might be of the delirious, confusional, maniacal, melancholic stuporous, or delusional type. He had very little personal knowledge of illegitimacy as a cause but called attention to Dr T S Clouston's statement that 75 per cent of the puerperal cases admitted to Morningside Asylum followed illegitimate births Another point in the etiology was that 26 per cent of the cases admitted to Bethlem Hospital had had a previous attack of insanity, either one before marriage or one after marriage, which was not puerperal in origin or a previous puerperal attack He said that alienists constantly found a history of previous "hysteria' in patients admitted to asylums which when carefully inquired into was found in many cases to have been a previous attack of definite mental disorder euphemistically called "hysteria." He was sure that such patients ought not to marry

Dr E W White thought that Dr Jones s proportion of occurring cases was too low, probably 1 in 400 confinements was nearer the mark, for there were many which did not go to the asylum for treatment and of which no records were obtainable He drew attention to certain of the mental symptoms and to the temperature charts in this disease. The obscene language, erotic tendency, and self abuse were probably of peripheral origin from abnormal uterine conditions, altered lochia &c In nearly all his cases there was an elevation of temperature of from one to two degrees in the evening, with a morning fall of a degree or less, lasting from ten days to a fortnight, then a subnormal temperature for several weeks. Frequent baths with scented soap were necessary on account of the perverted skin secretion.

Dr W S A Griffith stated that with regard to the insanity of pregnancy there was a group of cases quite distinct in which the main feature was the apprehension of the patient, either real or simulated, that unless the pregnancy was terminated she would become insane, he looked upon all such cases with the gravest suspicion, not of insanity, but of rather the reverse—namely, as an ingenious method of putting strong pressure on the medical adviser to produce abortion.

Dr T Seymour Tuke agreed with previous speakers in the necessity for good feeding and urged the early resort to artificial feeding if called for While admitting the great value of alcohol the danger of forming a habit must not be lost sight of

Dr T Claye Shaw referred to the question of the existence of a mental disorder due to the puerperal state. It appeared to him that there were two classes of cases really existent, but both characterised by the delusions, incoherence, and other mental symptoms supposed to be pathognomonic of insanity due to the puerperal state alone. Insanity characterised by prominence of sexual mental demonstration might occur in young women at the developmental epoch or in women of middle or advanced age in whom there were no uterine or ovarian complications of any kind to be passed through, just as delusions of a sexual character might be seen in boys and men accompanied by acts of masturbation, and yet there was no occasion to attribute the symptoms to influence from the genital organs at the moment. When, however, the temperature was higher than was usually met with in acute insanity and the symptoms came on shortly after parturition, there was a strong argument in favour of a direct connexion between the mental and bodily states, especially when there was a history of hereditary taint, together with the probability of the presence of a septic condition.

Dr J M. Amand Routh urged the desirability of having intermediate receiving houses, or a nursing home, where women suffering from such temporary insanities as those under discussion could be received and treated Such a plan would avoid the stigma of having been in an asylum and would make it much easier to get the friends of the patient to agree to her removal.

The President thought that obstetricians saw these cases, as a rule, at a much earlier stage than did the alienists. Perhaps for this reason, and because of the shortness of time, the introducer of the subject had said but little about diagnosis When the patient was admitted into an asylum the diagnosis had been made, but in the earlier stages it was not always easy to say that a case amounted to actual insanity He considered that the refusal of food was a far graver symptom and pointed much more certainly to insanity than did sleeplessness

Dr Jones replied briefly

Laryngological Society of London—A meeting of this society was held on Jan 9th, Mr E Cresswell Baber, the President, being in the chair—The following officers were appointed for the year—President Dr P McBride. Vice-Presidents Mr A A. Bowlby, Dr Dundas Grant, Dr P Kidd, and Mr C J Symonds. Treasurer Mr. W R. H Stewart. Librarian Dr StClair Thomson Secretaries Dr J Donelan and Dr E. Furniss Potter Members of the Council Sir Felix Semon, Mr E Cresswell Baber, Mr C A. Parker, Dr W Permewan, Mr R. Lake, and Mr. L A. Lawrence.—Sir Felix Semon exhibited a case (which had been previously shown at the November meeting of the society) of Ulceration of the Left Tonsil with Enlargement of Numerous Cervical Glands on both sides of the neck (? malignancy) in a man, aged 70 years. It was now seen that the ulceration had disappeared and that the tonsil had become much smaller, whilst the enlargement of the cervical glands had considerably diminished. Malignancy was now excluded The case was shown again as affording valuable evidence that ulceration of a tonsil in old people with enlarged glands must not necessarily he looked upon as malignant—Dr P Watson Williams exhibited new designs for Sphenoidal Sinus Cutting Forceps and a Laryngeal Spray—Dr A. Bronner showed a drawing and read notes of a case of Suppurative Ethmoiditis and Frontal Sinusitis after radical operation for Nasal Polypi. The nose had been curetted on three occasions with Meyer s ring knife Four weeks after the last operation the patient began to have pain, a high temperature, and became semi comatose. The nose and forehead became swollen Both frontal sinuses were opened and found to be full of pus The dura mater was exposed. The patient was relieved for 12 hours after the operation and then died. The anterior part of the left frontal lobe was found to be necrosed and there was extensive purulent basal meningitis—Dr H. L Lack showed a man, aged 59 years, with Aphonia of six months' duration who had a similar attack rn to the article under that heading, written by Kallius, d he will find it described as the treatment of organs d tissues with potassium bichromate for a variable ngth of time according to the effect required to be oduced, after which the sections are placed in solutions of nitrate of silver of definite strength or in solutions of mercury bichloride, when a finely granular prepitate occurs which is composed of chrom silver or chromublimate, enabling certain elements of the tissues, and ssentially the cells, when the preparation is properly leared, to be distinguished from others It is pointed out hat Golgi's method is best adapted for the investigation f embryonic structures. The details of the process are hen given, as, for example, the strength of the soluons to be used, the duration of exposure of the ssues to the action of such solutions, and the emperature at which they should be kept. The advanages of the method are shown to be that it is very enerally applicable, affording, when the successive steps re properly carried out, beautifully clear objects, whilst it as the further advantage that thick sections are more nstructive than excessively thin ones. The rest of the rticle, which extends over no less than 34 pages, is occupied with the numerous modifications that have been suggested by Cox, Sala, Hoyer, Ramon y Cajal, Obreggia, Pal, Greppin, Kallius, and many others, some being especially adapted for particular tissues, as, for instance, the nervous system, the muscles and the cornea. Finally, there is an excellent bibliography

The work is extremely carefully edited and when completed should be on every laboratory table, for it is convenient to have the data here given at hand and much trouble and disappointment will be saved by a reference to its pages.

The English Poor laws their History, Principles, and Administration By SOPHIA LONSDALE, Poor law Guardian, Lichfield Union. Third edition, revised and enlarged. Westminster King and Son. 1902. Pp. viii.-89 Price 1s. net.

EVERY medical man, and indeed every ratepayer ought to know something about the Poor law At the present time, especially when there are a number of able-bodied unemployed men in the East-end of London, it is most desirable that so pressing a question as their relief should be considered in the light of knowledge previously acquired. There is great danger that the money of ratepayers, and of the charitable public may be used in a manner which is not only useless but absolutely mischievous

Miss Sophia Lonsdale, who has had the experience afforded by the actual study of the Poor law in its practical working has written a little book which gives in small compass a very large amount of useful information. Three lectures which were originally delivered at the University Settlement for Women at Southwark have been revised, corrected, and brought up to date, and in their present form they will give to any intelligent reader a clear conception of the nature of the Poor laws and of the way in which and by whom, they are administered. Those who have not the leisure or wish to read the monumental work of the late Sir George Nicholls[1] will be able to get from Miss Lonsdale's book in a couple of hours a general and fairly correct outline of the causes which led to the making of the laws and a general knowledge of ' legal poverty" in England from the time of Elizabeth.

The most useful part of the work is contained in the third chapter where a very clear account is given of the actual everyday working of Poor law relief. There is a description of the workhouse with its officers, the master, the chaplain, the medical officer, and the porter (who "is supposed to prevent the entrance of objectionable things into the workhouse"). The various systems adopted for the education of pauper children are enumerated and briefly described. The peculiarities of vagrants are touched upon in sufficient detail, and evidence is brought forward to show that the shelters and refuges which have lately been provided by well meaning people in such profusion are by no means an unmixed blessing Indeed, it is said that not a few of these " moral elevators " are a disgrace to civilisation and in the case of many "the worst of our casual wards is a paradise in comparison to them " There are some valuable suggestions as to the best method of helping men who are out of work and it is pointed out that in any scheme which is to have a chance of success it must be recognised that "the unemployed are not all exactly alike." A thrifty man of good character may be temporarily out of work. Every effort should be made to keep such a man off the rates. On the other hand, the idle and vicious are best treated in the workhouse or by reforming agencies. It has been proved over and over again that indiscriminate outdoor relief imposes upon the ratepayers a burden too heavy for them to bear and tends to increase rather than to diminish the state of things which it is designed to remedy Examples bearing on these and on other points are very simply and clearly given by Miss Lonsdale, who in most, if not in all, cases mentions the sources of her information

The book might, it is true, be improved by further revision, but taken as a whole it is an extremely good piece of work written in great part from personal knowledge by a woman of clear insight, of acute observation, and of high intelligence. It is entirely free from foolish and hysterical exaggeration and would serve as a good literary model for His Majesty's Women Inspectors of Factories.

Text book of Electro-Chemistry By SVANTE ARRHENIUS, Professor at the University of Stockholm. Translated by JOHN MCCRAE, Ph.D London Longmans, Green, and Co 1902 Pp. 344 Price 9s. 6d

ELECTRO-CHEMISTRY is one of those branches of chemical science which has undergone immense development during the last 20 years and to Professor Arrhenius much of this progress is due. The effect of the electric current upon a liquid containing a metallic salt in solution was, of course, observed many years ago, the phenomenon being called "electrolysis." Faraday may be said to be the founder of electro-chemistry by his classic researches on the electrolytic deposition of metals, he having succeeded in establishing certain laws in regard to the phenomenon. But the phenomenon of electrolysis has gone a step further than merely illustrating the separation of metals from solutions of metallic salts, it has thrown light not merely on the nature of solution but, *a priori*, on the constitution of matter. Professor Arrhenius is perhaps the best living exponent of the marvellous development which we have indicated and with him should be mentioned Van t Hoff and Ostwald

The work before us is founded upon a series of lectures delivered by Professor Arrhenius at the University of Stockholm in 1897 The English translation, which is based on the German edition, has been admirably done by Dr McCrae. The translation into German of the original Swedish edition was made by Dr H. Euler and in that edition many valuable references to the literature of the subject up to 1901 have been added. In the same way Dr McCrae has made the English edition very valuable by appending a list of references to the recent literature on the subject. We find that the context contains references to recent work undertaken in this country such as that by Messrs. Heycock and Neville on the solutions of metals in each other The various sections of it and the tympanum. Roughly speaking the former was specially adapted to the relief of acute cases and the latter to the cure of chronic suppuration. The indications for the mastoid operation were discussed under the heads of acute and chronic diseases. Under acute diseases were included (1) acute middle-ear suppuration with invasion of the antrum, (2) an acute exacerbation in the course of a chronic suppurative otitis media, (3) influenzal mastoiditis, (4) secondary infection from a meatal abscess, and (5) acute middle ear tuberculosis Chronic conditions in which the mastoid operation was called for included (1) chronic suppurative otitis media, (2) recurring discharge, (3) facial paralysis, (4) cholesteatoma, (5) persistent mastoid pain, (6) meatal stenosis, (7) Bezold's mastoiditis, (8) mastoid fistula, (9) necrosis, and (10) as a preliminary to other operations.—A discussion followed the reading of the paper

---

[1] A History of the English Poor-law in Connexion with the State of the Country and the Condition of the People. By Sir George Nicholls, K.C.B. late Poor-law Commissioner and Secretary to the Poor-law Board Murray 1854

EDINBURGH ROYAL MEDICAL SOCIETY—A meeting of this society was held on Jan 16th, Dr Prentice being in the chair—Dr Peter McBride read notes on some Abdominal Cases which presented difficulty of diagnosis Three of them had been supposed to be intestinal obstruction but after examination they were diagnosed as gastro intestinal influenza, alcoholism, and distended bladder Another case with symptoms like those met with in gall stones was not diagnosed as the patient got well without operation—Dr T W E Ross read notes on a case of Œdema Glottidis, for which tracheotomy was performed The patient had symptoms of renal disease The cause of the œdema was doubtful.—A dissertation on Gait by Dr C M. Campbell was read in his absence by Dr H. J Dunbar After describing and analysing the mechanism of walking in a normal individual he showed the value of gait as an aid to diagnosis in some pathological conditions

GLASGOW NORTHERN MEDICAL SOCIETY—A meeting of this society was held on Jan. 13th in the Royal Infirmary—Dr John Macintyre gave a very interesting lantern demonstration on Electro-therapeutic Apparatus in the lecture room, with special reference to affections of the œsophagus and respiratory passages, after which the members inspected the new electric pavilion and were shown the apparatus and instruments—The meeting was brought to a close by a vote of thanks being accorded to Dr Macintyre and the superintendent of the infirmary

Reviews and Notices of Books.

Encyklopadie der Mikroskopischen Technik, mit besonderer Berücksichtigung der Farbelehre Herausgegeben von Professor PAUL EHRLICH, Dr MAX MOSSE, Dr RUDOLF KRAUSE, Dr HEINRICH ROSIN, and Professor Dr CARL WEIGERT Mit zahlreichen Abbildungen. Berlin Urban. Wien Schwarzenberg 1903 Abtheilung I., pp 400, Preis 10 Mark Abtheilung II., pp 400 Preis 10 Mark. (*Encyclopædia of Microscopy with Special Description of the Art of Staining* By Professor EHRLICH, Dr MOSSE, Dr KRAUSE, Dr ROSIN, and Professor CARL WEIGERT Two Parts, each of 400 pages, with numerous Illustrations. Berlin Urban Vienna Schwarzenberg Price 10*s* each part.)

AN incredible amount of time and attention has been bestowed upon the technical details of microscopy during the last two or three decades Sections obtained by mechanical means of the uniform thickness of a fraction of a millimetre of the various tissues have been examined in fluids like the aqueous humour and the physiological saline solution, which are as nearly as possible identical with the normal conditions, they have been exposed to the action of innumerable acid and alkaline solutions of different strengths, to the influence of salts of many metals, to alcohol of various degrees of specific gravity, to clarifying oils, and to numerous staining agents, and with each new agent or method new features in the tissues under examination are discovered and a better understanding of them is arrived at The application of potassium bichromate, the employment of osmic acid, the double and triple staining of Ehrlich and Weigert, the silver nitrate and gold methods of Golgi and of Ramon y Cajal, and the use of formol have all aided in establishing the prevailing conceptions of the structure of our bodies In the present encyclopædia the student, or, indeed, the professor, who is working at any special tissue will find full details of almost all the means that have been hitherto tried to exhibit the modifications that the cell undergoes in its progress to maturity, whether passing through its life isolated and free or uniting with others to form membranes or glands or the fibres of muscle or nerve, or incrusting itself with cartilage or salts to form organs of support. It is here shown that each tissue demands special treatment and that some play of the imagination is required to combine the varying appearances presented by the action of different agents and to obtain a general idea of the structure or organ under examination.

The reader must not expect to find in the pages of this volume a treatise on histology There is no connected account of the structure of any special organ. In the article "Haut" (Skin), for example, there is no such description as is contained in the works by Quain and Sharpey, by Gray, or in Schäfer's "Essentials of Histology," but he will find described the original method which Herxheimer employed to demonstrate the spiral fibres known by his name and the modifications suggested by Kromayer, Unna, Schutz, Mayer, and Delafield. He will find the different modes of showing the presence of eleidin and of pigment, the proper method of preparing nails and hairs for section, and the methods of exhibiting the characteristic features of favus, trichophytia, pityriasis, erythrasma, actinomycosis, blastomycosis, and cheloid acne. A long section covering 74 pages is devoted to the subject of injection, the various substances that have been used, as gelatin, gum, albumin, wax, tallow, asphalte, resin, paint, fusible metal, alcohol, and glycerine, are all given with the colouring agents which demonstrate the complexity and enhance the beauty of the preparation or, as in the case of the liver, aid in enabling the distribution of the vessels to be understood. Numerous forms of pumps and syringes are depicted and a section is devoted to physiological injection.

There is an excellent article covering 50 pages, entitled "Embryologische Technik," written by Herr Ballowitz of Greifswald This gives full details of all necessary proceedings for the study of embryology, including artificial fertilisation, the method of obtaining and observing the living specimen, the preparation of ova and embryos, the processes of fixing and hardening these exceedingly delicate objects, of staining and imbedding them, of cutting and mounting sections, and of the reconstruction of embryos on the completion of serial sections, with various experimental and operative methods Herr Ballowitz dwells on the importance of rapid removal of the developing ovum from the body of the parent It has been found that even in reptiles the young embryo rapidly breaks down, so that Dr Yoeltzkow found it necessary in his researches on the development of the crocodile in Madagascar to have the animals chained and dragged up to his house where he could open them and at once transfer the ova to the fluid used to preserve them. In order to obtain the ova in different stages of development a small opening was made in the abdomen and a string of the ova was extracted with the hand, all having arrived at the same stage of development. The wound was then aseptically closed and after two days was reopened and another batch of eggs was removed The rules for the application of the various fixing agents, such as osmic acid, chromic acid, corrosive sublimate, picric acid, nitric and acetic acids, platinum chloride, alcohol, and formol are then given, with the advantages and disadvantages attending the use of each

Again, should a young microscopist desire to obtain some information of Golgi's method of staining, he has only to has been reached and only attain a stage corresponding to that of the ripe proglottides of a tænia after having led an independent existence for a considerable time. The strobila is actively locomotive. Mr Haswell refers this cestode to the genus Phyllobothrium. 2. The Development of Lepidosiren Paradoxa, by J Graham Kerr, Regius professor of zoology in the University of Glasgow This is the third instalment of the papers on this subject by Professor Kerr and is devoted to the development of the skin and its derivatives The changes which the chromatophores undergo under alternate exposure to light and darkness are well described and well rendered in the plates illustrating the paper Separate sections are devoted to the stomodæum, the teeth, the hypophysis, and the central nervous system In the account of the brain of the adult lepidosiren it is shown that it closely resembles that of protopterus The cerebral hemispheres arise at two separate bulgings of the wall of the thalamencephalon, the pineal organ is simple without any trace of a separation of a part of it to form a "parietal organ." The rudiments of the eyes, nose, and ears are at first solid, the cavity of the optic vesicle arising secondarily, in the histogenesis of the visual layer of the retina the development of the rods is preceded by the formation of the oil globules. 3. The Metamorphosis of Corystes Cassivelaunus (Pennant), by Robert Gurney, B A. Oxon 4 Artificial Parthenogenesis and Fertilisation, a review by Thomas H. Bryce.

Analytical Records

FROM

THE LANCET LABORATORY

BROMOCOLL

(CHARLES ZIMMERMANN AND CO 9 AND 10 ST MARY AT HILL, LONDON E.C)

BROMOCOLL is an organic compound containing bromine which it is proposed to substitute for the ordinary alkaline bromides. It is a yellowish brown powder insoluble in water or acid fluids, but slowly soluble in alkaline fluids Bromocoll, therefore, is probably absorbed in the intestinal tract. It is stated that it gives the well known sedative effects of the alkaline bromides, while it is without injurious action, and its administration in the place of bromides in epilepsy in comparatively large doses is suggested Bromocoll used in the form of an ointment is said to be efficient in the treatment of irritable conditions of the skin as eczema and prurigo Bromocoll would appear to be a definite chemical compound containing tannin, gelatin, and bromine and is prepared by acting on gelatin with brominated tannin The drug is stated by several German physicians of repute to give encouraging results in sleeplessness epilepsy, and other nervous disorders

HUNTER BALTIMORE WHISKY

(W LANAHAN AND SON BALTIMORE A. A. BAKER AND CO 30 MINCING-LANE LONDON E C)

The following analysis of this rye spirit is interesting as showing relatively small amounts of secondary products of fermentation such as aldehyde, furfural, higher alcohols, and ethers. The results were as follows Extractives, 0 40 per cent, mineral matter, 0 01 per cent, alcohol, by weight 35 50 per cent., by volume 49 40 per cent, equal to proof spirit 74 30 per cent The secondary products given in grammes per hectolitre were as follows aldehyde, 3 50, furfural, 1 00, higher alcohols, 30 00, ethers reckoned as ethyl acetate, 34 30 The spirit is dark brown in colour and is intended to be taken rather as a liqueur than diluted with plain or aerated water It possesses the peculiar flavour and smell of rye spirit which in certain countries is much esteemed. Compared with malt whisky or genuine brandy the amount of higher alcohols, furfural, aldehyde, and ethers is small. From this point of view the liqueur is a very pure spirit—that is to say, it approaches the composition of diluted ethyl alcohol as do most grain derived spirits in general We may add that the alcoholic strength is somewhat low, and, indeed, half a degree lower than the limit of dilution of whisky permitted in this country

KARNOID PREPARATIONS

(KARNOID LIMITED 6 AND 7 STONECUTTER STREET LUDGATE-CIRCUS LONDON, E C)

We have already drawn attention to the excellent results obtained by that method of drying in the cold which is adopted in the preparation of Karnoid foods These products recently have been considerably improved as regards flavour An analysis of karnoid beef showed that it contained 55 per cent. of proteid and no less than 12 16 per cent. of albumin was extracted by cold water Chicken karnoid yielded in a similar way 13 64 per cent. of albumin. The clear cold water solution of karnoid turns into a sort of jelly on heating owing to the coagulation of the myosin albumin Karnoid meat preparations are excellent foods and admirably adapted for the requirements of the invalid They afford a ready means of preparing a really nutritious meat tea. We have also examined a preparation of oysters obtained by the same dry cold process Here, again, we found the albumin of the oyster in a soluble condition, the total amount of matter extracted by cold water being 50 per cent. and the amount of coagulable albumins 13 per cent. The dried oyster flesh was in a powdered form resembling white pepper in appearance This method of concentrating and comminuting fleshy foods is a great advance on other methods, since in the product are retained the vitalising principles of the original meats intact

IMPERIAL STOUT

(A LE COQ AND CO 25 ORANGE STREET LONDON S E)

This stout is described as "extra double" and our analysis confirms this description, assuming that this expression refers to stout showing a very high percentage of malt extractives The following was our analysis Malt extractives, 9 21 per cent. (containing over 8 per cent. of proteids), mineral matter, 0 45 per cent., alcohol by weight 9 36 per cent., by volume 11 61 per cent., equal to proof spirit 20 35 per cent. The sample we examined was in good sound condition and ripe and possessed a rich malty flavour It is free from excessive acidity and the carbonic acid gas is the product of the fermentation of the liquor itself and is not artificially forced in We have already expressed the opinion that artificially carbonated malt liquors are dietetically inferior to those which effervesce with their own natural gas of fermentation This stout it is stated, has been shipped hitherto exclusively to Russia. Stout has a reputation of being a very nourishing malt liquor and in this regard this specimen must be assigned a high position, since its analysis shows a very considerable proportion of nutritives.

(1) INVALID FOOD AND (2) TELMA COCOA

(THE TELMA SYNDICATE 57 FENCHURCH-STREET LONDON E C)

(1) The invalid food is stated to be prepared from malted lentils and malted wheat, a fact which is easily revealed by microscopic examination The food contains a large amount of soluble carbohydrates owing to the malted process and the digestibility is thereby increased Our analysis gave the following results Moisture, 5 08 per cent, mineral matter, 1 90 per cent, proteids, 17 24 per cent, carbohydrates and fat 75 78 per cent (2) Telma cocoa is a mixture of dextrinised cocoa with the foregoing food There is thus a dietetic gain, the cocoa adding some nitrogenous principles as well as stimulating substances Our analysis of the cocoa gave the following results Moisture, 5 79 per cent., mineral matter, 1 96 per cent., proteid, 20 72 per cent., carbohydrates and fat, 71 53 per cent These foods present the

the subject are dealt with in a lucid manner and notably so in the chapter in which the application of electrolysis to the separation and estimation of metals is described. Rules are laid down for the direction of the analyst who decides to adopt this convenient method of estimation Incidentally, it may be pointed out that the quantity of a salt in a solution may be determined by measuring its conductivity, and, further, the method can be applied to the estimation of two given salts in the solution "At high dilution all salts when applied in equivalent quantity conduct almost equally well." It is obvious from this fact that it is possible to find the weight equivalents of salts present, for instance, in potable water by determining the resistance The methods of electro-analysis might be employed with advantage in cases of metallic poisoning Thus copper, mercury, lead, arsenic, antimony, tin, and zinc could be recovered directly in the metallic state from the contents of the stomach The book deals with many other branches of the subject, as for example, the theory of accumulators and the utilisation of heat developed by the electric current, as in the manufacture of carbide of calcium, carborundum, and aluminium, and in other processes in which electrical appliances are employed A book of this kind written in the English language has long been wanted, and those who wish to gain an insight into the nature of electro chemical action and its applications have now the advantage of being able to consult a work by one of the first authorities on the subject

LIBRARY TABLE

Aids to Gynæcology By ALFRED S GUBB, M.D Paris, M R C S Eng London Baillière, Tindall, and Cox. 1903 Pp 136 Price 2*s* 6*d* —This little book, which is one of "The Student's Aids Series," has, we see, reached its fourth edition It does not pretend to be more than an 'epitome of the signs, symptoms, and treatment of the diseases peculiar to women," to quote the words of the author As such it will be found useful to the student and to the young practitioner, but for the former of course its use must be supplemented by some good text book

Aids to Forensic Medicine and Toxicology By WILLIAM MURRELL, M D , F R.C P Lond. Sixth edition. London Baillière, Tindall, and Cox. 1903 Pp 110 Price 2*s* 6*d* —This is another of "The Student's Aids Series " It is clearly written and if used as the author in his preface says that it should be used will be found to be of value. We are glad to see that Dr Murrell calls attention to the fact that all judges are bound to administer the Scottish form of oath without question if the witness so desires it

Herbert Fry's Royal Guide to the London Charities Edited by JOHN LANE London Chatto and Windus 1903. Pp iii.-294 Price 1*s* 6*d* —This valuable work becomes larger every year It might with advantage be reduced by eliminating details of certain militant "religious" associations which can hardly be described as charities But the inclusion of these is only a small blemish on an otherwise excellent compilation.

A Doctor's Thoughts By CLEMENT B GUNN, M D Edin Selkirk James Lewis 1902. Pp 100 —Dr Gunn, like 'Weelum McLure," is a Scots country practitioner His "thoughts" are embodied in a collection of sonnets of which most show a true poetic afflatus. To those who appreciate the beauty of nature and the romance of religion this little book will afford much pleasure

Carmina Medici By WILLIAM FINDLAY, M D Paisley Alexander Gardner 1902. Pp 166 Price 3*s* 6*d* net — Dr Findlay's muse plays on a rougher toned pipe than that of Dr Gunn But in this world action is more important for most of us than is contemplation and such poems as "The Hypochondriac" will go home to every practitioner's heart. Should, however, anyone, like Barnes Newcome, be drawn towards the domestic affections, let him read "A Spring Monody," and if he can do so without a lump in his throat we shall be surprised. The "Kirkyard Eclogue" on Glasgow Royal Infirmary is admirable reading and we are glad to see eulogies of three of our favourite writers—Henry Vaughan, Sir Thomas Browne, and Dr John Brown.

A Handbook of the Open-air Treatment By Dr CHARLES REINHARDT and Dr DAVID THOMSON London John Bale, Sons, and Danielsson, Limited. 1902 Pp 176.—This is the second edition of a useful book the first edition of which was reviewed in THE LANCET of March 2nd, 1901, p. 637 To this edition Dr David Thomson has added a short record of the history and results of the open air treatment. The list of sanatoriums has been brought up to date and at the beginning of the book sundry passages of interest to a patient suffering from pulmonary tuberculosis have been added

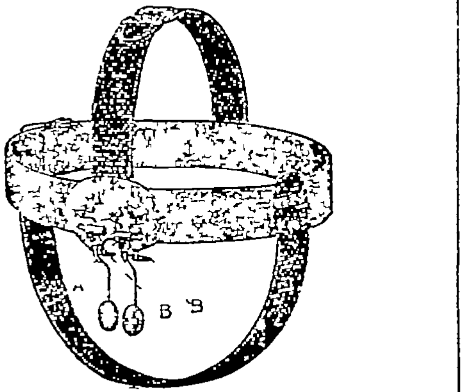
Glossaire Médical By Dr L. LANDOUZY, Professor of the Medical Clinic at the Paris Faculty of Medicine, Laennec Hospital, and Dr F JAYLE, Chief of the Gynæcological Clinic of the Paris Faculty of Medicine, Broca Hospital With five Maps and 426 Illustrations. Paris C Naud. 1902 Pp 663 Price, paper covers, 16 francs , cardboard covers, 18 francs —This is a dictionary of medical terms and expressions The authors urge that constant progress accomplished and numerous discoveries made in medicine and surgery result in the employment of so many new terms that a book of reference is much needed. Again the custom of calling an instrument or an operation by the name of the practitioner who first resorted to such instrument or operation does not help to indicate what the meaning of the term may be All this has given rise to a complicated medical language which no practitioner can be expected to know thoroughly Again, there is a difference between the words that might be employed and those that are usually utilised The glossary before us seeks to give what is practically useful , not so much all possible nomenclature or all the old terms, but rather all the modern words and expressions which are actually in vogue. It is a collection of new words, of anatomical expressions, of diseases that bear the personal names of their discoverers, of recent medicaments, of the principal mineral waters, sanatoriums, &c. To these words brief bibliographical indications are added and numerous small but well executed illustrations render the meaning more accurately than would be possible by mere verbal descriptions. Deformities and monstrosities constitute a large portion of these pictures, and as many of them are taken from life they are very interesting Then the maps give the health resorts, the sanatoriums, agricultural colonies for the convalescent, and the like. Altogether the work may be regarded as a very complete compendium and, considering that such technical works are generally very expensive, the price in this case may be described as moderate

JOURNALS AND MAGAZINES

The Quarterly Journal of Microscopical Science Edited by E RAY LANKESTER, F R.S , with the coöperation of ADAM SEDGWICK, M A , F R S , W F R. WELDON, F R.S , and SYDNEY J HICKSON, F R.S With Lithographic Plates and Engravings on Wood. London J & A. Churchill. 8vo New series, No 183 Vol. XLVI Part III. December, 1902 Pp 108 Price 10*s* —This part contains the following articles 1 On a Cestode from Cestracion, by W A Haswell, F R S The cestode here described is found in considerable numbers in the large intestine of that ancient fish, the Port Jackson shark. In it, as was noticed by von Beneden, the proglottides are set free from the posterior end of the strobila long before maturity op of the chamber immediately over the burner or fire. The esult of this arrangement is that a maximum amount of conensed liquid is obtained and according to our analysis this quid contains a very appreciable amount of sulphur in the orm of combined sulphuric acid In one experiment we btained 13 ounces of fluid after the stove had been working ix hours, the total gas consumed being 48 cubic feet—that s to say, approximately one ounce of fluid is obtained from hree cubic feet of gas consumed. On analysis this fluid was ound to contain seven grains per gallon of sulphuric acid SO_3) which is equal to about three grains of sulphur per gallon. There is thus an important amount of sulphur washed out of the products of combustion and as sulphur compounds are the most objectionable products of the combustion of coal gas this result is decidedly a favourable eature of the stove. As to the heating efficiency of the tove this need hardly be determined by experiment since all the possible heat of the gas consumed is entirely utilised for the purpose of heating a room The maximum reading of a thermometer placed one foot in front of he stove was 80° F The stove we tested consumed only eight cubic feet of gas per hour and on a very cold day it sufficed to raise the temperature of a room of 1500 cubic feet capacity from 55° F to 61° F in three hours Considering that only eight feet per hour were consumed and that the room was a difficult one to keep warm on account of spacious windows with a north aspect, this result is satisfactory The temperature of the room was subsequently maintained at 62° F for four hours, although the outside temperature fell to 48° F As might be expected, the amount of carbonic acid gas in the air increased, the actual increase after six hours being from 3 5 parts per 10,000 to 10 parts per 10,000 No attempt, however, at ventilation was made and the increase of carbonic acid gas under the same conditions, but with people living in the room, was in much the same progression. Even after several hours' working there is no evidence of the presence of those offensively smelling gases which point to defects in the working condition of the stove and the formation of which has served to prejudice so much the use of coal gas for heating purposes. The stove gives an efficient and healthy heat, the warmed air being quite free from smell or "stuffy" character and it is not "scorched." The Carron Company of Glasgow and elsewhere are the makers and the London agency is at 20 Victoria street, Westminster, S.W where various types may be seen in working order

A NEW FORM OF NASAL TRUSS

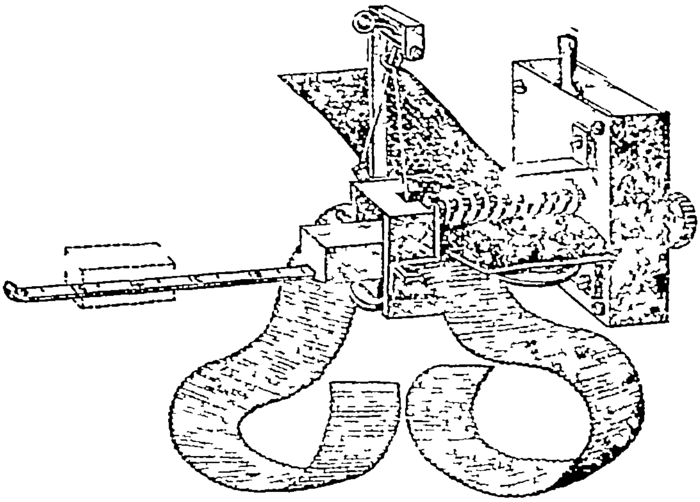
HERETOFORE the difficulty has been to prevent the forehead plate of a nasal truss from slipping from side to side and upwards over the forehead. The present truss is designed to obviate this difficulty by making the lower border of the forehead plate follow the contour of the root of the nose and contiguous orbital margins. A rounded notch A corresponding with the root of the nose is cut in the plate and the margins of the lower part of the plate forming the sides of the notch are bent backwards in a blunt curve, B B, to almost a right angle to the rest of the plate. The notch therefore embraces the root of the nose, while the turned back portions of the margins of the plates catch under the orbital ridges at the internal angular processes of the orbits This prevents the truss from being displaced upwards, while the notch prevents any movement from side to side. The truss is provided with the usual straps and head band, and to the plate are fixed the usual arms for making pressure upon, and fixing, the nasal bones or cartilages. It is made by Messrs. Arnold and Sons, West Smithfield, London, E C



Harley-street W W J WALSHAM, F R C S. Eng , &c.

IMPROVED RICHARDSON'S SPHYGMOGRAPH

HAVING found that the Richardson's sphygmograph was so constructed that it was not possible to apply a pressure of more than four ounces and that a pressure of one ounce was not always to be depended upon, I have suggested that certain alterations shall be carried out by Messrs Allen and Hanburys, Limited of 48 Wigmore-street, London, W , which will remedy these defects The steel bridge has been raised to permit the weight being pushed home beneath it where it does not interfere with the movement of the steelyard The figures indicating the pressure are read off on the steelyard on the distal side of the weight and not on the proximal as is customary A pressure of from one to six ounces can be easily seen and registered. The pressure indicated by each figure has been separately tested by the makers and found accurate.



J FLETCHER LITTLE, M.B Cantab , M.R.C P Lond.
Harley-street, W

ROYAL INSTITUTION—The Friday evening discourse at the Royal Institution on Jan 16th was delivered by Professor James Dewar the subject being Low Temperature Investigation One of the researches described was concerned with the formation of ice under a pressure of several thousand atmospheres. Among the various experiments he showed how a vacuum tube could be progressively exhausted so as to exhibit in a brief period all the phases of electrical discharge in rarefied air up to the production of Roentgen rays, the exhaustion being produced by cooling the tube in one spot with a little sponge soaked in liquid hydrogen

THE PLYMOUTH ROYAL EYE INFIRMARY—The annual meeting of the subscribers of this institution was held on Jan. 14th under the presidency of the mayor of Plymouth. The medical report showed that during 1902 there had been 2130 out-patients treated, 261 in patients admitted, and 309 operations performed. The financial statement showed that an unfavourable balance of £1076 remained, including £1000 standing against the building fund of the new infirmary The mayor made a strong appeal to clear off the debt on the building and contributed 10 guineas to start a special fund for that purpose.

general advantages of malted food and the selection of the constituents has been judiciously made. The pulse foods, for example, are much better digested when malted and mixed with wheaten flour

HUBBLE S BEEF BISCUITS (ST IGO)

(Alfred Hubble, 85 New Church road, Camberwell, London S E.)

Microscopical examination of these biscuits reveals the presence of a considerable amount of beef tissue and, in view of this result, it is not surprising that a high proportion of proteid was found. Our analysis gave the following results Moisture, 7 82 per cent., mineral matter, 3 97 per cent., proteids, 35 84 per cent. The balance may be accepted as consisting of starch and fat. The biscuits have a pleasant meaty flavour and are "short" and crisp They serve very well as a source of temporary nourishment in emergency As the analysis shows, they contain a high proportion of tissue-forming substance

HÆMATOGEN (HOMMEL S)

(Nicolay and Co 36 and 36a St Andrew's-hill Doctors Commons London E C)

We have already indicated in these columns the composition of Hommel's hæmatogen. The preparation contains the normal salts of blood plasma and is rich in unaltered albumin as is shown by the fact of the preparation turning nearly solid on heating Besides these important points hæmatogen also, of course, contains iron in organic form and partly on this account Hommel's hæmatogen has proved valuable in anæmic conditions. The preparation has recently been improved chiefly in regard to flavour Formerly it had a curious salty flavour which was distasteful to some persons This objection can no longer obtain.

VARIOUS CHOCOLATES

(Séchaud & Fils Montreux Switzerland London Offices Peninsular House Monument street, London E C)

We have received some novel specimens of chocolate from the above firm, one containing chopped nut, another coffee, and another milk The analysis of the milk chocolate was as follows Moisture, 2 5 per cent, ash, 2 25 per cent, fat, 27 90 per cent., and proteid, 7 30 per cent. The preparations are not only pleasant to the taste but they are also nutritive. The flavour of those chocolates containing coffee is decidedly novel

CASUMEN ARROWROOT

(Prideaux's Pure Casein and Life Food Co Motcombe Dorset)

The addition of pure milk proteid to arrowroot is a correct physiological proceeding since arrowroot is one of the most easily absorbed starches known, while casumen is a soluble proteid Moreover, arrowroot contains less than 1 per cent. of proteid, and alone therefore possesses no tissue-forming value, while casumen contains over 90 per cent. of proteid Our analysis of casumen arrowroot was as follows Moisture, 14 15 per cent, mineral matter 1 05 per cent, fat, 1 20 per cent., proteid, 28 20 per cent., and arrowroot starch 55 40 per cent. According to this analysis casumen arrowroot consists of arrowroot plus 30 per cent. of casumen. This 30 per cent. represents the gain obtained as regards nourishing value by mixing casumen with the arrowroot. It forms an excellent food for invalids and infants and for those possessing weak digestive faculty

JEYES SPECIAL FLUID

(Jeyes Sanitary Compounds Co Limited 64 Cannon street London E C)

We have at various times described the series of disinfectants prepared by Jeyes' Sanitary Compounds Co, the original preparation being known as creolin, a fluid coal tar compound which forms a uniform emulsion with water This company has recently prepared a coal tar disinfectant of a similar nature but with increased germicidal power which is known as Jeyes' special fluid.

According to the bacteriological experiments made by Dr E Klein, this new preparation is decidedly destructive to certain pathogenic organisms. The experiments related to the germicidal action of the fluid on staphylococcus pyogenes aureus in various dilutions and after varying periods of exposure of the micro-organisms to the fluid. In another series the germicidal power of the special fluid in various dilutions on tuberculous sputum was tested, the time of action being 24 hours, the *materies morbi* having been applied to the surface of wood. As is well known, the resisting power of the staphylococcus is an excellent guide as to the power of a given disinfectant. The results showed that even when the special fluid was diluted to the extent of 1 in 400 it proved a complete disinfectant for this specific organism in an exposure of five minutes. In the second series of experiments the sputum of a person affected with pulmonary tuberculosis was tried. There was no doubt of the presence of an abundance of the tubercle bacilli. The result of inoculation experiments on guinea pigs ultimately showed that the virulent tubercle bacilli deposited and dried on wood became completely disinfected by solutions of the special fluid up to 1 in 800 after an exposure of 24 hours. According to these results the preparation is obviously a trustworthy germicide.

New Inventions.

THE CARRON PATENT HYGIENIC INDUCTION CONDENSING GAS STOVE.

The heating efficiency of a gas stove depends of course upon the extent to which the total possible heat of combustion is realised. The greatest economy in this direction would be attained by allowing gas to burn in the open room and making no provision for carrying away the escaping products of combustion. There are, however, obvious objections to this method apart altogether from the fact that the combustion may be not completely satisfactory If the products of combustion of coal gas were only carbonic acid and water they would be no more objectionable than those arising from human respiration. Under such conditions, and all things being equal, the gas stove would sin less against the purity of the air than a human being However perfect the combustion of coal gas may be there are always sulphur compounds to be reckoned with and attempts have been made from time to time to free the products of combustion from these sulphur oxidation products. To some extent such purification is distinctly effected in what is known as the "condensing gas stove" of which that of the Carron Company is a decidedly improved type, giving a high heating efficiency on a very small consumption of gas and yielding products of combustion which in the main are condensed, the liquid so formed containing much of the original sulphur of the gas in the form of combined sulphuric acid. Carbonic acid gas is also in some measure condensed, while in a well designed stove practically all the steam is reduced to water The fact that the products of combustion are in this way largely condensed is not the only favourable feature of the stove, for in the act of condensation their heat is given up and made available for the purpose of warming. On this account the Carron condensing stove shows a very high heating efficiency and *a priori* the consumption of gas is small. The construction of the stove is very simple. Over the gas flame which may be of the argand or Bunsen type with a chimney, or over a red hot gas fire, an exit chamber is placed through which the gases pass and are expanded by the heat The gases then travel to the right and to the left to chambers at each side of the stove. Condensation occurs and vapour is produced. The top section of the stove is quite hot while the lower section is cold The hottest point, and therefore the greatest expansion, occurs roughly about half way down the condensing chamber Between the condensing chamber and the burner or fire on both sides are two tubes which carry off the vapour which is led to them by the hot gases formed at the careful in drawing up the terms of reference. These terms should specifically state that the object of the inquiry was to determine the best means of efficiently *applying* vaccination and revaccination, the desirability, or the reverse of revaccination should under no condition be the subject of discussion. But in our opinion the moment for legislation is opportune. We have a strong President of the Local Government Board supported, let us hope, by a strong Government The appointment of a departmental committee means postponement and then it becomes difficult to prophesy what may be the calibre of the Government which may be called upon to deal with this question, and what may be the fighting power of the then President of the Local Government Board—for a successful President of the Local Government Board usually passes to better paid offices, when public health loses a man who, had he stayed, might have done admirable constructive work While congratulating the Imperial Vaccination League and the Jenner Society upon the great success of their labours we must urge them, hether or not a departmental committee be appointed, to arry on the war The whole difficulty is merely one of rganisation, and vaccination has upon its side education, nfluence, and wealth. Let those who possess these advanages make use of them for the control of small pox.

The Medical Examination of Lunatics in Workhouses

THERE were 3425 insane persons admitted into the asylums of the county of London during 1901 the great majority of whom passed through the metropolitan workhouses in the process of being certified. In addition to these there was a large number of persons who, being admitted into workhouses as alleged lunatics, were, after 14 days detention, discharged under the advice of the medical men engaged in their examination. The examination of all these persons and the choice of the medical men employed therein are matters therefore, of very considerable importance, both public and professional When a relieving officer or overseer of the parish removes a person alleged to be of unsound mind to the workhouse he forthwith lays information before a justice of the district who is bound under the statute to summon a medical man to his aid to examine and to report upon the mental condition of the alleged lunatic. The choice of the medical man who is summoned and also the amount of the fee which has to be paid to him by the guardians rest entirely with the magistrate There is nothing in the statute to guide him in this matter it being assumed that most of the justices will be enabled to find such guidance in common sense and reason as applied to the duties of their responsible office It is therefore a matter for the gravest regret when complaints can be made upon good ground that the chief reason for the selection of the medical man is that he is the ordinary medical attendant or personal friend of the justice concerned. The majority of the metropolitan justices employ the medical officer of the workhouse, being apparently guided in their choice by the fact that the alleged lunatics are under his care and constant daily observation, whereas any outside practitioner can of necessity only make special and occasional visits to patients who are under the care of another medical man It has been alleged in some quarters as a reason for not employing the medical officer of the workhouse that the latter might be induced to certify lunatics for the sake of the fee. But the fee is paid for the medical opinion and report, quite apart from the nature of that opinion, whether for or against the sanity of the patient, so that the fallaciousness of this stupid accusation is apparent The Commissioners in Lunacy have expressed the eminently reasonable view that the proper person to certify as to the sanity or insanity of an alleged lunatic is the medical attendant of the patient for the time being, and in the case of inmates of a workhouse this is certainly the medical officer If it could be shown that any individual practitioner had had, previously to being employed by the justice, special experience in lunacy this might be brought forward as a reason for his being called to the case by the justice But it is alleged that sometimes the practitioner is employed merely because he happens to be a personal friend or the medical attendant of a justice, and where such relations between the justice and the examining medical man form the only reasons for the medical man's selection we have a grave abuse of authority The medical officer of the workhouse is nearly always possessed of special experience not only of Poor law lunacy but of the character and habits of the particular social class to which the patient belongs and the community ought not to be deprived of his valuable services upon the amiable impulse of a justice desiring to oblige a friend In view of the complaints which we have received the matter should, we think, be brought to the notice of the Commissioners in Lunacy, or, in the event of the expression of their opinion not having sufficient weight with the justices, before the Lord Chancellor

The Medical Officer of the Ballachulish Slate Quarries

As we have already stated in THE LANCET[1] Lord KYLLACHY has given his decision in the action raised in the Outer House of the Court of Session by the Ballachulish Slate Quarries Company, Limited against Dr LACHLAN GRANT, whom the directors of the company sought to prevent from continuing to practise medicine in the district of Ballachulish. Dr GRANT was under contract to attend the workmen of the company by virtue of an agreement made with the directors in which he bound himself to accept a month's notice to terminate his services and further to give up any other appointments which he might then hold in the neighbourhood and to discontinue all practice there. It was not, presumably, contemplated by Dr GRANT when he made this agreement that he might be dismissed under it arbitrarily or without proof of any default on his part, and consequently when he found himself in receipt of a notice which he considered to be so given he refused to carry out the portion of his arrangement relating to practice in the district. Judgment has now been given against him and he

THE LANCET.

LONDON SATURDAY JANUARY 24, 1903

The Deputation of the Imperial Vaccination League

THE members of the deputation from the Imperial Vaccination League which waited upon Mr LONG at the Local Government Board on Jan. 14th must have been highly gratified by the cordial sympathy with which they were met, indeed, we can recall no other instance in which the programme of a deputation has been so unconditionally accepted. An account of the proceedings will be found at p 260 of our present issue. It is a matter of satisfaction to THE LANCET to find that the President of the Local Government Board was able to agree with the views set forth by us in our leading article of Jan 10th, and we were pleased to see that Mr LONG urged upon the deputation the necessity of the continuance of its crusade if it wished its proposals to be carried to, and through, the House of Commons Mr LONG was, however, careful to guard his position as a Minister of His Majesty's Government and member of the Cabinet He told the deputation that he had not yet consulted his colleagues and that even had he done so he would have deemed it undesirable, politically speaking, to reveal his plan of campaign for the edification of the opponents of vaccination. In our leading article, to which Mr LONG referred in his reply to the deputation, we urged upon the Imperial Vaccination League the desirability of approaching some of the leaders of the Opposition in order that when the Government proposals are made known they may not become the subject of party polemics, and although the President of the Local Government Board seems to have some misgivings as to the practicability of a non contentious measure, we are still of opinion that the effort should be made to confer with the leaders of the Opposition The support of Sir MICHAEL FOSTER Sir WALTER FOSTER, and Dr FARQUHARSON ought to be secured.

The question arises whether Mr LONG'S influence in the Cabinet will suffice to convince his colleagues of the wisdom of his convictions Although the President of the Local Government Board presides over a department which exercises the predominant influence in domestic legislation and which is responsible for the public health of the nation, this department, unfortunately, does not occupy a very high position in the eyes of the Government As Sir MICHAEL FOSTER remarks in the current number of the *Nineteenth Century*, it has been accorded by the State an inferior status in "the hierarchy of Government Departments.' Until the President of the Local Government Board receives the rank and pay of a Secretary of State it can hardly be expected that the county and district councils and boards of guardians will take that position in publi affairs which the importance of their work demands. Th reference to local authorities brings us back to the questio as to whether Mr LONG S decision to transfer the administration of the Vaccination Acts to county councils and count boroughs is the best possible one Since the deputatio took place several suggestions have been made to u upon the subject, and it is clear from the number an sincerity of these proposals that there is some want o unanimity upon the matter among local authorities an their officers as to what is the best scheme. It i suggested by some that the administration should be lef in the hands of the guardians but that county council should be given a supervising power, and that, should th necessity arise, such county councils should be able t supersede the guardians in administration. One o the arguments used in support of this view is that the vaccination officers, who are very frequently relieving officers, are already under the guardians and that a transference of administration to the county councils would place the unfortunate officials under two masters. There is, of course, something in this view, but it seems to us that the claim that vaccination should be a thing quite apart from the disabilities real and imaginary, of the Poor law is so strong that the difficulties of detail would have to be greater than we think them to be to justify us in foregoing an important advance in principle. As a matter of actual fact, the vaccination officers have now frequently three masters—i.e., the guardians, the Local Government Board, and the registrar general—for vaccination officers are very frequently also registrars of births and deaths. If the county councils are brought into fresh relations with boards of guardians a step will be taken which may tend towards a far greater complication of local affairs than obtains at present. We think that the interests of the county councils in matters of sanitation should be deeper, and that vaccination, being a detail of public health administration, had better be put in their charge. We have already alluded to the advantages in this respect which they will possess under the Education Act

Some of those who have placed their views before us strongly advocate the appointment of a departmental committee to consider the administrative problems involved, the idea being to make certain that the Government proposals, when framed, will constitute a strong measure founded on first-hand knowledge of the facts We see the force of the suggestion, but are afraid tha the step would mean the postponement of the difficulty Even if the suggestion were acted upon at once the committee might take a considerable time to get into working order The number of witnesses to be examined would in all probability prove to be great, and before the report could be prepared and presented the legislative crisis would have been passed and the present Vaccination Act would be extended for at least another year A departmental committee might, we allow, smooth the passage of a Vaccination Bill, but we have some qualms in mentioning a departmental committee since this is such a very favourite device with Governments of all shades of opinion for shelving awkward questions Certainly, if such a committee were appointed it would be necessary to be very infamous Mrs DYER, who was hanged in 1896 after a series of cold blooded murders, has thrown a more lurid light upon the details of this revolting traffic than the trial of the two women SACH and WALTERS, which was concluded at the Old Bailey on Jan. 16th by the passing of the death sentence upon both the accused. It was shown for the prosecution in the course of the case that the guilty women worked in connexion with one another, being in constant communication and sharing the profits of their transactions, while the whole of the circumstances taken together proved beyond any reasonable doubt that each knew and connived at the acts of the other. SACH kept a "maternity home," including in her advertisement of it the statement "baby can remain." Women—in every case, probably, women to whom motherhood meant ruin—came and were delivered at SACH'S "home." Where their natural feelings for their offspring made them hesitate to dispose of the infants SACH allayed any scruples that they might feel by specious assertions of her power to get the infants adopted into good homes in return for small payments. Immediately after birth the children were taken from their mothers and handed to WALTERS who removed them to her own lodgings. In the particular case of the murder upon which conviction has followed a few drops of chlorodyne deprived the newly born infant of life and the disposal of the body alone remained to be considered. Probably the method with which we are familiar from reading about it frequently in newspapers was the one which WALTERS intended to employ. She meant to leave the infant's body in a parcel at a railway station or in a railway carriage, but she had already excited the suspicion of a police officer who resided in the same house, with the result that she was arrested at South Kensington station with the corpse in her possession. The arrest of WALTERS was immediately followed by that of SACH and the statements of the two women were such as to render it lawful for the prosecution to give evidence of other similar cases at the trial on an indictment dealing with the death of one child only, and the circumstance secured the just conviction of both the miserable wretches. When evidence was forthcoming that other children had been born under SACH'S auspices and transferred to WALTERS who had disposed of them in some way or other of which no explanation was forthcoming, and when it was proved that one such child had been seen dead in WALTERS'S arms in a coffee shop, the possibility of the death which led to the arrest of the prisoners having been due to an accidental overdose of chlorodyne became too remote for acceptance. Similarly it became clear that SACH, though she did not herself kill the children, could not have been ignorant of their fate. It was left open to the accused to prove that they had in fact procured the adoption of infants by well to-do people in accordance with their proposals to the mothers, but this they were unable to do. Upon proof of the clearest sort both women were therefore found guilty of murder and justly condemned to death.

From time to time Acts of Parliament have been passed with a view to protect the lives of infants from baby farmers, and the most recent statute, passed in 1897, was an improvement to some extent upon its predecessors. The policy adopted by the legislature has been to make it necessary that persons undertaking the care of infants for hire should give notice of what they are doing to the local authority, so that their proceedings may to some extent become the object of supervision and inspection. It is easy to see that the operation of such laws as these can be evaded by a little ingenuity and secrecy on the part of those who ought to give the required notice, but SACH and WALTERS apparently conducted their business in such a manner that they were not in the eye of the law baby farmers at all. SACH purported to be the manager of a maternity home and WALTERS to be the agent for the transference of the infants to foster mothers, neither according to her own statement was a baby farmer. The second section of the Infant Life Protection Act 1897, orders that any person retaining or receiving for hire more than one infant under the age of five years for the purpose of nursing or maintaining such infants apart from their parents for more than 48 hours shall within those 48 hours give notice to the local authority. There was no evidence that either SACH or WALTERS ever had upon her hands more than one child at a time, or that the children ever remained with either of them for so long as 48 hours alive. It was further their custom to undertake the entire charge of the children intrusted to them, thus ridding their parents of them in consideration of a sum of money paid down. The obvious dangers of traffic of this kind have attracted the attention of the legislature, but here, again, SACH and WALTERS were safe from supervision without any need to break the law. The fifth section of the Act already referred to provides that notice shall also be given within 48 hours to the local authority by any person retaining or receiving an infant under the age of two years on consideration of a sum of money not exceeding £20 paid down and without any agreement for further payment as value for the care and bringing up of the said infant. SACH and WALTERS made their profits larger and at the same time kept themselves outside the scope of this section by the simple process of exacting from the parents of their victims more than £20. With the child of whose murder they were convicted they received £25, and in the case of one of the witnesses examined £30 had been paid, but they would have been equally safe from the obligation to notify their proceedings had they taken £20 0s. 6d. It would be interesting to know who posted these women in the law, and by enabling them to escape lesser penalties has conduced to their conviction for a capital crime. We have entered into the legal aspects of baby farming with some detail because it behoves our readers to be aware of the existence of bogus maternity homes and of the possibility of their being instituted with the intent to defeat the objects of the laws for the regulation of baby-farming.

The following are some of the conclusions to which the facts proved at the trial of SACH and WALTERS seem almost inevitably to lead. The difference made by the law between the baby farmers who take charge of several children at a time and those who take one at a time only is not justified by any comparative safety of the single child, and the child adopted in consideration of a larger sum than £20 needs the same protection as that accorded to the infant for whom humbler provision has been made. It has to be recognised that a number of women, not all of them poor in the sense has been held to be bound by the contract which he unquestionably made. It is possible, no doubt, that an appeal may lie and that points of law raised before Lord Kyllachy may be argued again in a higher court. Whether this be so or not we do not propose to discuss these but to assume the present decision to be final, while we would point out to medical practitioners how undesirable it is in their own interests and in the interests of the public that they should bind themselves by rigid contracts of this kind without fully understanding their import and being prepared for all their possible consequences.

We have suggested what may have been in the mind of Dr Grant He may have considered that the directors of the quarry company, in the interests of their workmen, desired to provide against the unpleasant contingency of their medical officer proving at some future date to be negligent or incompetent in the performance of his duties, and that they accordingly protected themselves by means of a prompt and easy method of getting rid of him. Confident in his own competence and integrity he, no doubt, felt no anxiety lest summary dismissal should at the same time deprive him of his practice at the quarry and of that which he was evidently likely to acquire in the district Others would perhaps have thought as he did. Some, more prudent, would perhaps have demanded the insertion in their contract of an undertaking by the directors not to exercise their power to terminate the engagement except for causes which would not have been difficult to define. Such a demand might not have been acceded to, but the refusal in itself would have been a warning of what might be expected to occur, and such a warning could have been disregarded or not according to the choice of the medical man. We see no reason, however, why the candidate for such a post should not occupy as strong a position as those seeking to obtain his services Men of ability are not to be had for the asking, taking into consideration the emoluments offered and the limited possibilities of future additions to them in a district such as that of the Ballachulish Slate Quarries. Whatever the conditions may be, however, which may influence the directors of a company employing workmen to dispense with the services of their medical officer they are likely to be such as directly concern the contracting parties only The objectionable feature of an agreement which binds a medical man, as Dr Grant was bound, is that it indirectly affects a whole district by making the medical man who is perhaps most easily available for its inhabitants, if not the only practitioner within their reach, the servant of a body of traders who can retain him or get rid of him as they please but who have no interest in his presence or absence, or, indeed, in his existence, except in so far as it affects themselves. We have already pointed out[2] that Dr Grant has filled the post of Poor law medical officer of the Ballachulish district That the directors of a quarry company may properly have a voice in the choice of a medical officer for their men may be conceded—although in this instance the Ballachulish quarrymen entirely deny that their directors can claim any right whatever to interfere—but no one can hold that the directors of such a company ought to be able to appoint and summarily to dismiss the Poor law medical officer of the locality in which they happen to carry on business

We quoted in The Lancet[3] upon a previous occasion a statement or manifesto of the directors which professed to assign as the cause of Dr Grant's dismissal a defect in his contract. The contract appeared not to prevent him from taking work at a distant granite quarry, and we pointed out that the quarry said to be objected to was not in our opinion so far distant as to make this a valid excuse. We have also referred[4] to other circumstances which are said to be connected with the giving of the notice. These, we observe, are freely written and spoken of in the district apparently without any satisfactory reply being made to the very serious allegations put forward. The more recent developments of the dispute, however, show a state of affairs still to be deplored, while at the same time they confirm the position of those who maintain that the notice given to Dr Grant was not given for any good cause. In consequence of a resolution passed by the men and handed to the manager of the quarry the men have been "locked out" and deprived of their means of living They had, however, before this addressed to the shareholders of the company, who are apparently only 27 in number, a statement of their case and appealed to them in the hope, as they expressed it, that the shareholders' sense of right and justice may guide them to make an effort to terminate an unrighteous and unmeaning persecution of a respected, upright, and honourable man. To such an appeal we can only add the very strong recommendation that the shareholders should not dismiss the question lightly, and that they should not give their support to their directors, or, indeed, to the men, without full investigation of all the points that have been raised. We would further remind them that although men are within their legal rights who claim the full advantage of a bargain made, legal rights may sometimes be foregone without disadvantage or discredit to those who exercise such forbearance. In this case Dr Grant and those who sympathise with him only ask for such consideration and forbearance as justice will be found to demand after full inquiry has been made

We have no desire to be harsh in our judgment, but the impression left by a perusal of the whole of the materials available to us is one distinctly unfavourable to the directors of the Ballachulish Slate Quarries Company upon the broad question as to whether they have carried out their portion of the agreement between themselves and Dr Grant in the spirit in which such agreements should be carried out by all the parties to them. With regard to the agreement itself Dr Grant may be legally bound by it, but its terms are not such as, in our opinion, should be offered to members of the medical profession or accepted by them without their full purport being made clear upon the face of the document.

◆

Baby-Farming

Several recent criminal trials have drawn attention to the danger with which infant life is threatened by the practice of "baby-farming," but none since the case of the a ridiculous one It is also an impertinent one. Dr comes *to the conclusion that the whole report is* hing but an advertisement and thinks that it is only right let it be known, but Dr Lee is not an unbiased judge. haps he will withdraw the accusation of commercial dis- testy which he has categorically brought against the tors of this paper now that he has received a quite un- essary assurance from us of the independence of our ions And perhaps he will not Whichever course he may pt is quite indifferent to us, as we know that our readers l believe us when we say that his suggestion that our estigation into the brandy trade of Cognac was undertaken oblige the spirit-merchants is a childish one.

THE METROPOLITAN WATER-SUPPLY

HE report on the condition of the metropolitan water- ply during the month of November, 1902, has been ently issued by the Water Examiner The Thames river ter was in good condition from the 1st to the 27th days the month and of "indifferent quality" on the 28th, 29th, l 30th. The rainfall at West Molesey during the month ounted to 1 66 inches. The average daily supply de ered from the Thames was 133,297,668 gallons, from the *20,492,701* gallons, from "*springs*" and wells 55 628,188 lons, and from the Hampstead and Highgate ponds 685 lons. The total average daily supply was 209 419,142 lons for a population estimated at 6 435,126 and this resents a daily consumption per head of 32 54 lons. The Chelsea Company delivered the largest daily ount per head (40 28 gallons) and the East London mpany the smallest (26 82 gallons) The Chelsea, East ndon, Grand Junction, and Kent Companies delivered a aller, and the Lambeth, New River, Southwark and uxhall, and West Middlesex Companies a larger average ily quantity than they did during the corresponding month the year 1901. It may be remembered, however, that isons have been given in THE LANCET which make it ubtful to suppose that it would be wise to place implicit ist in the figures given in the report of the Water aminer On this point it may suffice to refer to the notes ven in THE LANCET *of* Jan. *10th*, 1903, p 116, Nov 15th, 32 p 1336 and Oct. 18th, 1902, p 1065 and to add that explanation has yet been given as to the curious cumstance that water from the Langham Hotel well found way into the mains of the West Middlesex Water mpany During the month of November the East ndon Company obtained supplies of water from the uthwark and Vauxhall Company "*and from the New* ver Company aided by the Grand Junction and West ddlesex Companies." The Water Examiner states that e average daily supply passed on by the Southwark d Vauxhall Company amounted to 8 723,333 gallons and at the quantity passed on by the New River Company if spread over the whole of the month was equivalent to average daily supply of 4 981,100 gallons.' Another count of the sources of supply of the East London Com ny is given on page 8 of the Water Examiner's report der the heading, Details of the Metropolitan Water- pply and Works of the Water Companies for the month November, 1902. In column 5 of this table, under the ading, "Average Daily Supply during the Month— allons," the following statement appears in reference to the mpany Supply from river Lee and storage 4 041,673, om Thames, 8 611,000, from wells, 16 *320,327*, *from* anworth springs, 1,601,000, from Thames, per Southwark id Vauxhall Company, 8 736,000" It will be noticed that gures on the same subject given in different parts of the port are not identical. No explanation is given as to how happens that the discrepancy occurs The proportions of rown tint in samples of water observed in a two-foot tube ranged from two to 16 degrees of the standard in use. In many of the former reports of the Water Examiner it has been stated that all the samples of water collected at the works of the companies were efficiently filtered," but the Water Examiner has never said on what authority the statement has been made, and although the question has been asked several times in THE LANCET it has never been affirmed that any sample of water collected at any "works" of any metropolitan water company *has ever been* sub- mitted for analysis to Dr T E Thorpe, F R S, the chemist to the Local Government Board. The November report of the Water Examiner does not contain the time honoured paragraph concerning efficient filtration to which allusion has just been made. In its place occurs the following sentence "All the samples of water collected at the works of the *companies* were clean, bright, and free from suspended matter" It would be interesting to know whether samples of the water of the East London Company's Thames filtering station were examined on Nov 28th, 29th, and 30th, and if so by whom. The Water Examiner does not say on what authority he makes the statement we have quoted. Dr T E. Thorpe fully examined a sample of the East *London Company's water which was taken on* Nov 10th, and samples of all the other companies' supplies collected on Nov *11th.* It is *unfortunate that* no full examination was made of the supplies during the period at which the Thames river water was in "an indifferent"—*that is to say*, a muddy—condition (Nov 28th, 29th, and 30th) Dr Thorpe found in the case of the samples which he fully examined that *the relative* amount of organic impurity contained in them could be represented numerically as follows Kent, 9, New River, 12, East London, 18, West Middlesex and Grand Junction, 26, Chelsea and Lambeth, 27, and Southwark and Vauxhall, 29 All the Thames-derived supplies were found to contain more organic matter than did the corresponding samples examined in October, and the water of the New River *Company* contained less than half the average organic impurity found in the Thames supplies. In the case of the East London Company's water taken at Lee *Bridge* and "representing the filtered Lee supply," Dr Thorpe found considerably less organic matter than in the Thames-derived supplies. Dr Thorpe, we should imagine, has fallen into a slight error if he believes that the water at Lee Bridge correctly represents the filtered water of the river Lee. According to the account given by the engineer of the East London Company during the month of November the amount of water taken from the river Lee and storage was only a little over 4,000,000 gallons daily, whilst the amount derived *from* wells *was over four times that* quantity, and unless we are *mistaken* the water filtered at Lee Bridge is a *mixture* of river and well water It is, however, to the Thames stations of the East London Company and especially to the water there filtered whilst the river is muddy, that we would again direct the attention of Dr Thorpe should the question be within his province.

WHAT IS A QUALIFIED NURSE?

THE departmental committee appointed by the Local Government Board to inquire into the question of workhouse and infirmary nursing and the difficulty which had been experienced in obtaining an adequate supply of nurses for the Poor law service proposes to answer the above question in a somewhat novel manner, and in a way which we venture to think deserves the careful attention of those who are interested in the occupation of *nursing* as a whole and the standard of workhouse nursing in particular Paragraph 90 of the committee's report *proposes to recognise* as '*minor training* schools" any of the smaller workhouses which possess (1) a superintendent nurse of the workhouse or a matron of of being actually indigent, are desirous of getting rid of their children to do so is of vital importance to them in gaining their livelihood. The people who relieve these parents of their offspring act from sordid and not from benevolent motives The baby farmer's profits by honestly carrying out the trust undertaken are likely to be but small and they can be increased only at the expense of the adopted infant, whose death, where a single and final payment has been made, is the most lucrative issue for which the baby-farmer can hope Insurance of the child's life, if it can be effected, may increase those profits, but infant life insurance in relation to the present method of death registration is not being considered here, as, for obvious reasons SACH and WALTERS did not draw attention to their schemes by attempting to insure their hapless victims' lives. It has before now been urged in THE LANCET that all so-called hospitals and nursing homes, where profit is made out of the care of the sick and helpless, should be subject to systematic inspection and supervision. In the case of SACH and WALTERS the lying in home kept by the former was an institution the conduct of which concerned herself alone A medical witness at the trial had attended confinements there but stated that he was only called to cases of special difficulty It will therefore be seen that in the majority of births occurring at this establishment there was no witness even to the child's existence except persons whose interest was best served by concealing it. The cheap and easy access of women like WALTERS to concoctions containing poison is another element of danger to infant life. Chlorodyne is readily obtainable and preparations sold as sedatives for ailing children are known even by the most ignorant women to be capable of causing death if given in excess, while the plea that the excess was an accident is likely to be accepted by a merciful jury if there is no evidence to rebut it It is fortunate in the interests of justice that in the case of SACH and WALTERS the evidence of similar transactions resulting in the disappearance of other infants was forthcoming to preclude the possibility of their innocence

Annotations.

"Ne quid nimis"

THE NEW INEBRIATES ACT

WE regard the working of the new Inebriates Act, which came into force upon Jan 1st of this year, as very hopeful in some directions, though in others the results that will be obtained are rather doubtful. For example, of the wealthy classes no one will be affected by the penal clauses, save, perhaps, the very young rich man who drinks in public—a character, we are glad to think, that is becoming rarer day by day as public opinion in the services and the universities declares itself more strongly against drunkenness The poor will be benefited despite themselves, but the rich will be able to avoid the reforming action of the law The Act will be far less efficacious in its operation in cities than in country districts In large towns it will be impossible to keep erring individuals from obtaining liquor and the process of notification will be almost a dead letter Still, as the law courts have begun to show, even in such a city as London an active police by arresting drunkards can do good. The village drunkard should cease to exist, for in villages police notification will prove almost a total barrier to the obtaining of liquor. On the whole the Bill should tend to lessen the number of inebriates. Mr F S D Hogg, the superintendent of the Dalrymple Home at Rickmansworth, estimates that over 50 per cent of those admitted into retreats for inebriety owe their downfall to sociability, and it is obvious that by far the greatest amount of social drinking takes place in public houses. Some social inebriates may be driven by the penalties into secret drinking, but many more will be saved from the woeful penalty that is paid for a too expansive and too facile geniality A dipsomaniac, whether regular or periodical, and whether his lapses into excess are frequent or infrequent, will, we expect, continue to drink, regardless of consequences He may make some attempt to conceal his habit, but not much good can be expected from such a course. With regard to the clause which provides for a legal separation between husband and wife on the ground of habitual drunkenness of one or other partner its working is bound to be beneficial to the community A certain number of persons will be relieved from a life of martyrdom and a certain number of children will obtain a chance of decent up bringing in a respectable home, which has hitherto been denied to them. In addition, the possibility that a separation may ensue if the vicious habit is not broken will send to retreats inebriates whom no form of persuasion has hitherto constrained to seek such help We should not, in fact, be surprised to learn that this clause of the Act proves a strong inducement to many to become total abstainers.

"THE LANCET AND ITS COMMISSIONS"

WE have received a letter from Dr Robert Lee of Gunterstone road, West Kensington, which is addressed to us on the envelope and within to the *British Medical Journal*. We do not pretend to guess for which journal Dr. Lee's letter was intended, but it has fallen into the right hands so far as his purpose is concerned For he wrote it (presumably) for publication and we give to it with cheerfulness the publicity which we are certain that our esteemed contemporary would not have granted —

> ### THE LANCET AND ITS COMMISSIONS
>
> *To the Editor of the British Medical Journal.*
>
> SIR,—There is something about THE LANCET Commissions which is not quite agreeable There is a kind of advertising tone about them, of a very subtle nature for while they promote the interests of one class they injure others unfairly and this is most difficult to read between the lines, until the advertisement and samples arrive The Report of a LANCET Commission goes out as part of the journal then a short time after a copy of the journal is sent for no particular reason as far as I can make out and then later another copy with the name of the firm or company interested in some particular statement in the Report to which attention is drawn and perhaps some sample of the article is sent along with THE LANCET The conclusion one comes to is that probably the whole Report is nothing but an advertisement and that the claim THE LANCET makes to be perfectly independent is not consistent with the way in which the Report is used as advertisement. If a journal lays itself open to suspicion it is only right to let it be known. The *British Medical Journal* happily has not run this risk.
>
> Yours, &c.,
> DOUBTFUL.

Dr Lee is, we suppose, referring to the investigations lately conducted by our Commissioner into Cognac and Brandy Substitutes. The value of that work to the medical profession and the public was widely acknowledged in the press and led the great growers and importers of Cognac brandy to send copies of THE LANCET to certain members of the medical profession whose addresses are in the Medical Directory and in some cases to offer samples of their produce. But of course THE LANCET had nothing to do with any of this. We gave no addresses, we sent no samples, we mailed no copies, we had no communication whatever with those who did so, and the suggestion that our action in the matter was taken in collusion with the proprietors of certain brandies certainly be the portion of all such infamous persons. Phillips's case was not as bad as that of Oslar, for he does not seem to have been personally responsible, but considering that a homeless vagabond constantly gets three months' imprisonment for ' sleeping out" it is a scandal that men can get off with a money payment when they have, in the pursuit of money only, deliberately tried to poison their fellow creatures.

THE NEW PRINCIPAL OF THE UNIVERSITY OF EDINBURGH

WE congratulate Sir William Turner upon his appointment as Principal of the University of Edinburgh in succession to Sir William Muir Sir William Turner's long and distinguished services to his *alma mater* as a professor are rightly recognised by this call to the head of the University His sound business qualities, energy, and tact, which have been so much in evidence in his conduct of affairs as President of the General Medical Council, may be invaluable to the University of Edinburgh in the present crisis in things educational.

THE CUTANEOUS EXCRETION OF CARBON DIOXIDE AND WATER IN MAN

WHILST the excretion of carbon dioxide and water from limited areas of the skin has been the subject of repeated observations the quantity of these substances eliminated from the whole surface has rarely been examined. The well known researches of Gerlach, Reinhard, Ersmann, Fubini, and Rorchi made on limited areas demonstrated, speaking generally that the excretion of water is increased either by a rise in the external temperature or by a diminution in the relative moisture of the surrounding air whilst that of carbon dioxide is clearly subject to the influence of varying temperature, so that with a higher temperature more carbon dioxide is discharged. Aubert and Lange inclosed the whole body in a chest with the exception of the head and passed through the chest for two hours by means of a pump a continuous stream of air free from carbon dioxide, the quantity of which was estimated in the air escaping from the chamber The temperature in their experiments varied from 29° to 33° C, and the average quantity of carbon dioxide estimated to be eliminated in the 24 hours was 4 grammes, or a little more than 60 grains Temperature was shown by these observers to have great influence on the discharge of the gas, for at 29·6° C only 2·9 grammes were eliminated in 24 hours, whilst in the same period at a temperature of 33° C no less than 6·3 grammes were thrown out. Schierbeck, experimenting in a similar manner on persons sitting naked and clothed, found that in the latter case below a temperature of 33° C (91° F) the perspiration remained insensible, but at higher temperatures than this sweating commenced. In those who were clothed much more insensible perspiration was given off than in those who were naked. Without clothes 22·2 grammes of water were eliminated per hour at 29·8° C 27·8 grammes at 30·4° C, and so on proportionally to 38·4° when 158·8 grammes were eliminated. Schierbeck came to the conclusion that when clothed and at rest and at a temperature of 32° C the total perspiration amounted to from two to three litres in 24 hours In regard to carbon dioxide, Schierbeck found that it remained nearly uniform between 29° and 33° C, and amounted to about eight grammes in 24 hours. On exposure to temperatures above 33° C the quantity eliminated rose rapidly so that at about 34° C it was nearly double. The subject has again been taken up by E. A. von Willebrand, who gives the results of his inquiries (made in Professor Tigerstedt's physiological laboratory at Helsingfors) in the last part of the *Scandinavisches Archiv für Physiologie* for the year 1902. In the first series of researches the elimination of water was estimated at temperatures from 12° to 30° C In a second series the temperature of the air admitted to the chest in which the person experimented on sat varied from 18° to 31·5° C Each experiment lasted for about two hours and the subject was a healthy man, 26 years of age, who weighed 68 kilogrammes. At 12° C the insensible perspiration amounted to 10·52 grammes per hour and at 28° C it was 27·25 grammes per hour The graphic curves which are plotted out show that the excretion of water by the skin by insensible perspiration when the body is at complete rest rises slowly and proportionally to the increase of the temperature in the surrounding air from 12° C to some point between 30° and 33° C when sweating occurs In regard to the elimination of carbon dioxide the experiments show that the excretion of this gas by the skin when the body is at complete rest remains unchanged between 20° and 33° C, being about seven or eight grammes in 24 hours, but where the temperature rises so high as to cause sweating—that is to say, at about 33° C—the discharge of carbon dioxide is suddenly doubled or even trebled. It may be added that von Willebrand agrees with Krause and Donders that the insensible perspiration is essentially a physical process and is the result of simple evaporation from the surface of the skin Sensible perspiration or sweat is, of course, the secretion of the sudoriparous glands

REFORM IN BURIAL INSURANCE

THE crime for which the women Sach and Walters now lie under the death penalty has revealed to the public of how little importance infant life is to a certain section of the community and Mr Justice Darling has done good service by directing attention to the present system of child insurance in a case which recently came under his notice. This arrangement, with whatever motive and reason it may have been initiated, has the disadvantage of making no adequate provision for the safety of the child. As the case now stands a parent can only recover invested money by the death of the child and, moreover, the sum insured is frequently in excess of that which would be required by many poor parents or guardians of children for actual burial expenses As events have proved, insurance has in very many cases gone hand in hand with neglect and illness conducive to a fatal issue. Mr Justice Darling's protest in favour of fresh legislation on this subject is practically identical with that of numerous tongues and pens which for years past have striven to bring about a fairer arrangement. It is truly remarkable with what foresight even poor, idle, and dissipated parents, while denying their younger children the barest, most obvious necessaries of life, are still able to maintain an insurance for burial expenses. Too much, perhaps, has been made of the alleged necessity for such a provision in the case of death among the children of the poor Funeral expenses under such conditions need not exceed a very small sum indeed The bulk of such outlay if used at all in connexion with the burial would probably be employed upon matters of entirely secondary moment which might be to a great extent dispensed with. When not so used, a frequent alternative, it represents money in the parents pocket, not, it is reasonable to suppose, without a possibility that it will quickly find its way to that of the neighbouring publican. There is a widely prevalent impression that such a course as this describes the circulation of burial insurance money in a large number of cases The possible peril to a child's well being is obvious, and this danger, illustrated as it has been by the teaching of experience, has aroused a feeling in favour of reform which continues to gain in strength. A legislature which has done so much to remove the evils which beset the lot of children, and especially of poor children, may well be the separate infirmary, and (2) a medical officer who engages to devote some of his time to instructing probationers by lecture or otherwise, and in which (3) systematic instruction is given by the superintendent nurse *or* (the italics are ours) medical officer which complies with the general plan to be laid down by the Local Government Board At the end of one year s training under these conditions the candidate is to receive a certificate, and it is proposed (paragraph 91) to create a new grade of nurse under the title of "qualified nurse." Even in thoroughly well equipped and well organised training schools, such as those which are attached to the metropolitan hospitals, a nurse cannot become really qualified to exercise her calling in so short a time, and the absence in small workhouses of a sufficiently varied number of cases and of modern methods of treatment and appliances renders the suggestion that she should be called a "qualified nurse" almost ludicrous. It will, indeed, be regrettable if the Local Government Board should sanction the recognition as qualified nurses of women who would hardly be trained in the elements of nursing

THE REMOVAL OF THE VERMIFORM APPENDIX WHEN THE ABDOMEN IS OPENED FOR DISEASE OF OTHER ORGANS

IN the *Journal of the American Medical Association* of Oct. 25th, 1902, Dr Howard Kelly has discussed the important question, Should the vermiform appendix be removed when the abdomen is opened for disease of other organs? The relation of the vermiform appendix to pelvic surgery was suddenly brought before his attention in 1894 by the case of a patient under his care for general pelvic discomfort and dysmenorrhœa He performed laparotomy and found a retroflexed uterus, adherent ovaries, and a relaxed vaginal outlet He suspended the uterus, ligatured the varicose ovarian veins, and repaired the vaginal outlet, but the patient was little, if at all, improved. Some months later she had an attack of appendicitis and was operated on by another surgeon with complete relief of all her symptoms Evidently the source of her troubles was the appendix. Since this experience Dr Kelly has never opened the abdomen without examining the appendix whenever it was possible to do so without enlarging the incision or running the risk of conveying infection to healthy parts. Out of a series of 115 cases he has found the appendix adherent to the right tube or ovary in 10 cases, involved in adhesions in 37, congested in three, and obliterated at the base in one case. Only 64 appendices were normal Dr Kelly has sent a circular to the principal American surgeons requesting an answer to the question, "Is it advisable to remove the apparently normal appendix whenever the abdomen is opened for other reasons, or whenever an incision is made in the right lower quadrant?" The majority replied that they do not remove the normal appendix during an operation performed for other reasons, but always remove it if it is even slightly adherent to other organs or if though free it is abnormally long—a practice which Dr Kelly indorses He does not remove the normal appendix for the following reasons 1. The operation would slightly increase the risk of danger, shock might occur at any moment and the additional five minutes consumed in the removal might have serious consequences 2 There are no statistics to show that the existence of a normal appendix involves a definite risk per mille either of death or serious disease. 3. The appendix may have some function. As Dr Robert Abbe asserts that the normal appendix never contains fæcal concretions, Dr Kelly advises that if such can be felt the appendix should be removed, even though it appears healthy He considers, further, the question whether the appendix ought not always to be removed when operations are performed near the cæcum which might give rise to adhesions In men the risk is slight but in operations on the uterus or right ovary the appendix may become adherent to the recent wound. Dr Kelly has observed five such cases, in which the appendix was subsequently removed. In four the appendix adhered to the stump of the right ovary and in one to a wound in the uterus from myomectomy Dr Kelly advises that whenever the right ovary is removed the raw stump should be protected by covering it with peritoneum and burying it out of sight. In all right-sided pelvic operations he also removes long free appendices, because an appendix which hangs free from the cæcum and is long enough to reach the field of an adjacent operation may become adherent and thus render the patient liable to an attack of appendicitis

THE ST BARTHOLOMEW'S HOSPITAL APPEAL

AT a meeting of the special appeal committee of the governors of St. Bartholomew s Hospital held at the Mansion House on Jan 19th, the Lord Mayor being in the chair, it was moved by Sir Trevor Lawrence, the treasurer of the hospital, seconded by Mr B Cohen, M.P, and carried unanimously —

> That having regard to criticism upon the proposed appeal for the enlargement of St. Bartholomew s Hospital based on inaccurate information a committee be appointed to report (1) whether it is desirable in the public interest and on financial grounds to retain St. Bartholomew s Hospital on its present site (2) in the event of the retention of St Bartholomew's Hospital on its present site whether any better scheme of rebuilding than that suggested by the governors can be devised (3) upon any other matters affecting the hospital that the committee may think it desirable to inquire into And that such committee consist of 15 members nine to be nominated by the Lord Mayor and six by the treasurer of the hospital and that the treasurer and the Lord Mayor be *ex-officio* members of such committee.

We think the resolution an eminently sensible one and congratulate the special appeal committee upon having adopted it unanimously St Bartholomew's Hospital has incurred criticism at the hands of many people woefully ignorant both of general matters in hospital administration and of the particular affairs of the institution and it is well that the public should know what a strong and carefully selected committee has to say upon the whole situation. We take it for granted that the committee, a majority of which will represent the public, will be strong and carefully selected, and that its report will be made upon an exhaustive examination of the facts.

GARBAGE-MONGERS

AT the Guildhall on Jan. 19th John Oslar of Denver Lodge, Nazeing, Essex, farmer and butcher, was summoned for sending to the Central Meat Market two quarters and two flanks of diseased meat, intending it for sale as human food. The meat came from a cow which had belonged to a Mr Dean living in the neighbourhood of Nazeing This cow accidentally strangled itself in its stall and was found dead. The carcass was dragged out into the yard and "stuck," when a little blood flowed. A knacker was summoned to take the carcass away, but on his way the knacker called on Oslar and asked him "if he could do with it." Oslar consented, paid the knacker 20*s*, and promised a load of hay in addition. He dressed the meat and sent it to market. Dr W Collingridge said that the meat was filthy and horrible. Oslar was fined £50 and costs or two months' imprisonment. On the same day, at Westminster, Enoch Phillips of Sloane-street, Chelsea, was summoned by the Chelsea borough council for exposing for sale as food on Jan. 9th a large quantity of game and poultry which was unfit for food Dr Louis C Parkes said that the game was lying in ice and water, it was sodden and putrid. Defendant was fined £10 and two guineas costs. We have said over and over again that persons who sell or try to sell putrid meat for food are neither more nor less than potential murderers. No fine is heavy enough, punishment and imprisonment with hard labour should ycism in the human subject have been known since the ; of Fabricius in 1618 and considerably more than cases have now been recorded. The first case ve recorded is typical of the condition except that an r glass form of stomach is very rarely found The pro- ; is usually though not invariably permanent. Various lanations have been suggested. Dr Müller regards the dition as atavistic in origin, while Dr Ferrannini explains case as a gastric neurosis. Dr Alt supposed that the con on was an attempt to correct defective primary mastica of the food which is very frequently observed in these s. Others have suggested mimicry as the explanation of family associations of this condition, but in Dr Müller s s, no one of the three was aware of the condition in relatives.

THE MEDICAL DIRECTORY FOR 1903

'HE issue of Messrs J and A. Churchill's valuable lical Directory for the current year presents some new tures The size of the page has been enlarged to royal avo, whereby the thickness of the volume is reduced, ile the date of the year is stamped on the two side covers well as on the back. The total number of names for 3 is 37,291 as against 36 788 for 1902 an increase of Of departmental increase the most marked is in the nber of Irish practitioners, the number for 1903 being 1 as against 2587 in 1902 Registered practitioners ident abroad have increased from 3952 in 1902 to 4117 1903. The introductory articles are decreased by the appearance of the article on the Army Medical School, tley but increased by an article upon the Medical Staff llege R.A.M.C Two other articles appearing in this ir s issue are a list of royal commissions dealing with dical and public health questions and a list of London oners. The Medical Directory is not generally supposed be a humorous work, but we have derived unfeigned usement from the classified list of books advertised in the lowing pages (viii.–xxxv) The catalogue, which we will at the outset is exceedingly useful is divided into head s and subheadings, and it is the latter which are so aint. Thus we find Beale s Liver, Foxwell's Liver, ndle s Surface, West's Chest, Woakes Deafness, Fenwick's ethra, Scott s Urine Campbell s Flushing Luff's Gout, evor's Diseases, Beale s Morality Haig s Uric Acid, rris' Ringworm, Bryant's Breast, Eccles Imp Descended tis and Bland Sutton s Ovaries. Notwithstanding the provements in the Directory the price remains the same as retofore and Messrs Churchill are to be congratulated on the continued excellence of their publication.

TABES DORSALIS A STUDY OF 140 CASES

THE medico-statistical study of nervous disease has made nsiderable progress during recent years. An interesting atistical study of 155 cases of tabes dorsalis by Dr Byrom ramwell was made the subject of an annotation in HE LANCET[1] in May last. Professor Joseph Collins of ew York has published in the *Medical News* of Jan. 3rd, 903 an account of tabes dorsalis based upon a personal udy of 140 cases Of these 52 were private patients, 47 ere hospital patients and 41 were dispensary patients. lany of these patients had been under observation for pwards of ten years so that something could be learned reference to the prognosis As regards sex 124 were ales and 16 were females, a ratio of 15 males to two emales. Of the males 12 were single, 78 were married nd 12 were widowers, no facts being stated concerning he rest. Of the females, six were single, six were married nd four were widows The average age of onset of the disease was 38 years 22 cases began between the ages of 20 and 30 years, 48 cases between 30 and 40 years, 45 cases between 40 and 50 years, and 14 cases between 50 and 60 years In one patient the symptoms began at the age of 18 years and in another at 60 years The age of onset was earlier in women than in men, 50 per cent of the female cases occurring between 20 and 30 years of age, as compared with 11 per cent of males for the same period Syphilis was ascertained to have existed in 85 males, or 68 per cent., while in 19 more its presence was probable though not certain The syphilis is said to have been slight in 80 of these cases. Of the 16 female cases some denied syphilis, but it was ascertained by inquiry that several of them had contracted it from husbands or lovers and that 11 of them, or 70 per cent., had thus been positively infected As regards alcoholic habits, it was found that 42 of the 140 patients had been intemperate drinkers Traumatism as an etiological factor was found only in five instances, one of these following a street car accident. In only seven cases could mental or physical overstrain be ascertained to have played a part in the etiology "The preponderating influence of syphilis," adds Professor Collins, "is shown in cases of tabes affecting both husband and wife, of which several cases were met with" A survey of the medical literature of Germany, Great Britain, and the United States is also added and seems to bear out this statement. As to the *modus operandi* of syphilis in bringing about tabes Professor Collins states that we know very little. All we do know of the pathogenesis of tabes may be, he concludes very briefly summed up it occurs in civilised mature men and women who have had syphilis and in children who have inherited syphilis, but why it occurs we do not know

THE PREVALENCE OF SMALL-POX.

AT a meeting of the Wigan board of guardians held on Jan. 2nd the following letter, addressed to the clerk, was read from Mr William Berry, medical officer of health of Wigan —

> Dear Sir —In consequence of the outbreak of small pox in one of the lodging houses of this borough and the further prevalence of the disease in the towns surrounding Wigan I beg to call the attention of your board to the necessity of vaccination and revaccination as the only true prophylactic measure known I wish to suggest that it would be well to revaccinate those officers of the workhouse who have to deal with the nomad class which is answerable for its introduction into the town It would be well also that the inmates of the workhouse should have the opportunity of being revaccinated. I do not think it necessary for the present at all events that the guardians should make special arrangements for the purposes of revaccination but I should like it to be made known that the public vaccinator is willing to revaccinate any person who applies to have the operation performed I am informed that recently the tramp wards have not provided ample accommodation for the numbers who have sought a night s lodging and if this is so it is very desirable that the medical officer of the workhouse should have the opportunity of examining and revaccinating them before sending them out to the common lodging houses in fact it would be well to compel the tramps who have not recently been revaccinated to submit to the operation before giving them a night s lodgings

Mr Fairhurst thereupon moved that the letter should lie on the table and Mrs. Alice Johnson seconded this motion The latter also asked, "Don't you think that if they had a good bath it would be better than vaccination?" She also is reported as saying, 'There is nobody but the doctors to benefit by vaccination That is why the doctors have so much to say about it" Eventually a resolution was carried that Mr Berry should be informed of the receipt of his letter and that the board was taking all precautions to prevent the spread of the disease. Now it is unfortunately a fact that no board of guardians has any power compulsorily to vaccinate tramps or anyone else but it is also a fact that small pox is often spread by tramps and that more especially in the winter Mrs. Johnson is, we suppose, an anti vaccinationist but her remark about "nobody but the doctors benefiting by vaccination" is a piece of silly rudeness We have no information as to what the board of guardians is doing to expected to interest itself in providing necessary safeguards against the abuse of this form of insurance. What measures may be best adapted to this end remains to be considered. We are of opinion that the present method, by which the insuring party receives a certain sum in the event of a child's death, is not the best possible On the other hand, every useful purpose would be served by an engagement which would guarantee the payment of all *bonâ-fide* expense incurred for burial up to a certain money value The parent could thus reap no advantage from the death of a child, while, on the other hand, the only legitimate object of insurance would be fully provided for

THE RELATIVE WHOLESOMENESS OF POTABLE SPIRITS

IT is generally admitted that age not only gives an agreeable or palatable character to potable spirits, such as genuine brandy or whisky, but also renders them more wholesome The chemistry of these spirits, however does not simplify with age, indeed, as a rule, it becomes more complex. Therefore, it can hardly be assumed that because a given spirit is chemically purer than another it is more wholesome. If the degree of wholesomeness of a spirit depends upon its simplicity of composition obviously the most wholesome would be chemically pure alcohol, and grain spirit approaches much more nearly to the composition of chemically pure alcohol than does malt whisky, rum, or genuine brandy Chemically speaking, starch, or what is nearly the same thing, grain, transformed by a hydrolytic agent such as sulphuric acid into sugar, instead of by the agency of an enzyme or ferment, yields a much purer alcohol than does barley that has been malted and converted into sugar by the diastasic process Still less pure, chemically speaking, is the spirit derived from the very complex fluid wine, and yet who will assert that genuine old brandy is less wholesome than whisky? In short, the alcohol obtained from grain by a rapid chemical process is much purer than that obtained from barley malt or the grape by what may be called a slow natural process After all, the natural process is a chemical one, but the distinction, however, remains that whereas in grain spirit the alcohol is the product of the fermentation of an artificially prepared sugar which is very pure, malt whisky and brandy owe their existence to more or less naturally derived sugar which is associated with other things These sugar associates contribute the characteristic flavour to the spirit. We may thus account for the differences between brandy, rum, and whisky, and malt whisky and grain spirit. Pure grain alcohol is without flavour and by itself unpalatable, and therefore for drinking purposes it must be flavoured by blending with it genuine old whisky or brandy This means, in other words, that the bulk of old whisky or brandy is considerably increased by adding grain spirit to it It is an act of dilution much as is the addition of water to milk. It is the old story of substitution, but we maintain that when malt whisky or brandy is demanded it should be supplied, apart altogether from the question whether grain spirit is more wholesome than malt or grape spirit. The physiological action of potable spirit though largely, of course is not entirely, that of alcohol. A carefully conducted chemical analysis distinguishes one spirit from another to some extent by revealing variations in the amounts, or it may be the absence of secondary constituents or what the French chemists call "impuretés" It is reasonable to suppose that if there are chemical differences there must be physiological differences also and experience shows that such is the case. Moreover, analysis also indicates differences existing between the composition of raw and matured spirits, but in this case the difference of physiological action is much more marked than chemistry is able at present to explain. What is needed in order to throw light upon the question is a series of physiological or personal experiments in which the effects of absolutely pure ethyl alcohol could be observed and compared with those obtained with all classes of potable spirit. So far however, experience is in favour of matured spirits being made from materials such as grape malt, and sugar, which are resolved slowly into alcohol by the aid of natural agencies and without resort to chemical operations, the only justification for which is to expedite the process and thus to cheapen the product.

IMPUDENT QUACKS AND THE NAME OF THE LANCET

IN THE LANCET of Sept. 20th, 1902, p 829, we exposed an improper attempt made in New Zealand to appropriate the name of THE LANCET in respect of a so called influenza cure. Our solicitors in due course communicated with the offending drug company who, in a very ungracious manner, have replied saying that they have destroyed all the labels and printed matter to which we took exception Later we had to complain[1] of the use of the name of THE LANCET by a firm of druggists at Bombay This firm on a communication being made to them promptly destroyed the labels in respect of which complaint was made and signed an adequate apology

HUMAN RUMINANTS

AUTHENTICATED cases of rumination in the human subject are of sufficient rarity to be interesting and worthy of note. Dr L. R. Müller of Erlangen, in the *Münchener Medicinische Wochenschrift* of August 5th, 1902, records three cases occurring in one family in the persons of a father and his two sons with a necropsy in the case of the former In this case the act first began at the age of six years and persisted till the death of the patient in his fiftieth year He had always been a rapid feeder, swallowing his food incompletely masticated, while about 15 to 20 minutes after the end of the meal the act of rumination commenced and lasted for from half an hour to one hour The food substances were returned to the mouth at intervals of from three to four minutes, were masticated and re swallowed, they possessed their natural taste, and only during and after this process did the patient derive any sense of enjoyment from his food. If the act were voluntarily prevented a disagreeable sensation in the stomach supervened. No other gastric symptoms occurred till about six months before the death of the patient, when pain with persistent vomiting and rapid cachexia led to a diagnosis of malignant disease of the stomach This was confirmed at the necropsy when an "hour glass" condition of the stomach was found, the septum being the site of the cancerous growth and the œsophagus and cardiac orifice of the stomach were dilated to such a degree as to admit three fingers From the appearances presented by the stomach Dr Müller concluded that the hour glass condition was not the result of the growth Two sons of the patient, the younger of whom was 22 years old, had also regurgitated and re-masticated their food, although the father was not aware of this Another case is recorded by Dr Ferrannini in the *Riforma Medica* of Oct. 11th, 1902, in a young man of neuropathic tendencies in whom both solids and liquids returned, as in the former case the regurgitated materials had their natural taste, they were alkaline in reaction. The motor, digestive, and absorbent properties of the stomach were otherwise natural. Cases of rumination or sanitary defects which exist in the large towns of America as well as in *those of the old world.*

[1] THE LANCET, Dec. 13th 1902, p 1653.

CHOLERA IN EGYPT

THE following figures show the distribution of cases of, and deaths from, cholera throughout Egypt during the week ending Jan 5th. During this period 6 cases of *cholera occurred,* against 49 in the previous week, thus showing a diminution of 43 cases. During the same week 2 persons were found dead out of hospital and 3 persons died in hospital, against 13 *deaths out of* hospital and 19 deaths in hospital in the previous week, thus showing a total diminution of 27 in the number of deaths. The 6 cases of cholera mentioned above occurred at Alexandria, there having been the same number in the preceding week. During the week ending Jan. 12th no cases or deaths from cholera occurred throughout Egypt

THE WEATHER AND THE STREETS

DURING the *first frost of this winter we called* attention in THE LANCET of Dec 13th, 1902, p. 1645 to the disgraceful condition of the streets under the care of the City of Westminster With the recent return of cold weather the matter at last penetrated to the council chamber and at the meeting held on Jan 15th the question was discussed. Dr H. A. Des Voeux and Mr MacConnell both gave evidence as to the dangerous condition of the streets, the latter referring especially to Hyde Park Corner *He* had made inquiries and was told that there was no ballast As we have said before *Westminster* is addicted to the use of salt. This is an odious custom True it removes ice, but the removal only substitutes a cold slush, and owing to the hygroscopic qualities of salt the road never dries. Lord Doneraile said that he could not agree that there was no ballast We do not know whether there is ballast or not, but anyway the authorities of Westminster do not put it down. The matter was referred to the works committee and there we suppose it will stop, especially as the frost has for the present disappeared. It never seems to strike the authorities that damp greasy roads such as existed during the first four days at least of this week are *almost as slippery* as *frozen roads* and in the Strand and the adjoining streets no ballast has been put down, with the result that fallen horses have been many Not very far from Westminster is a place called Kensington, here is being erected a new building called the Victoria and Albert Museum Tons of gravel have been displaced to make way for the foundations of this building, and we have no doubt that the Westminster authorities could buy some of this if they so desired. One member said that the Westminster council was 'bossed" by its officials. All we can say is that if the Westminster *officials* do not do as they are told they had better, as Mr MacConnell suggested, be dismissed.

Mr Frederick James Quick of Eltham, and late of Trinity Hall, Cambridge, *senior partner of* the firm of Messrs. Quick, Beek, and Smith, of 148, Fenchurch street, London, E.C , coffee dealers, who died on Dec. 21st last, has left his residuary *estate to the University* of *Cambridge* in trust to apply the income in the promotion of the study and research of vegetable and animal biology The University will eventually receive about £50,000 or £60,000.

THE annual *dinner of* the British Gynæcological Society will take place at the Café Monico, Piccadilly-circus, London, W , *on Thursday,* Jan. 29th, at 7 for 7 30 P M. The President, Sir John Halliday Croom, will occupy the chair Tickets, price 10*s.* 6*d.* each, may be obtained from the secretary, Dr J H Swanton, 40, Harley street, Cavendish square, London, W Ladies may be invited as guests.

Sir Michael Foster has publicly announced that the answers which Sir John *Rotton has* received *to* the inquiry made on his behalf have fully assured him that he may feel justified in renouncing his intention to resign his seat as Parliamentary representative of the University of London.

THE usual course of post-graduate lectures will be delivered at the Brompton Hospital for Consumption on Wednesdays The opening lecture of this session will be delivered on Jan 28th, at 4 P M., by Mr Stanley Boyd, whose subject will be Pleural Effusions and their Surgical Treatment.

Mr Thomas Sutton Timmis of Allerton, near Liverpool, has vested a sum of *£10,000* in *trustees* for systematic research into the origin and cure of cancer The research will be undertaken at the Liverpool Royal Infirmary and in the laboratories of University College, Liverpool

TENTH ANNUAL REPORT (FOR 1901) OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON

[FIRST NOTICE.]

THE *publication of the* local returns of the recent census has been promptly and judiciously *turned to account by* Mr Shirley Murphy in the compilation of his tenth annual report just issued. In this volume he has given an account of the vital statistics for 1901 of the administrative County of London, a record which derives additional value from the fact that all the rates are calculated on the population figures for that year The census returns have been still further utilised by him for the preparation of a life table for London, based on the enumerated population at the censuses of 1891 and 1901, and on the mortality in the county during the intervening period. The report before us, with diagrams and appendices, covers about 150 closely printed folio pages and, like its predecessors, it is divided broadly into two sections the first mainly statistical and the second administrative It is impracticable, within the space at our disposal, to do more than to notice the former of these sections and this we propose *to do by distributing the* matter over two articles, the first dealing with the recent outbreak of small-pox *in London and the second treating* of the general vital statistics and *sanitary condition of the metropolis* during the year 1901 and its nine immediate predecessors.

The epidemic of small pox, which is now *practically* at an end in London, although the disease still continues to spread in certain other parts of England, commenced in 1900 During the period which has since elapsed the presence of the disease in the midst of the densely crowded and ill-vaccinated populations of our poorer districts has caused grave anxiety and very serious trouble and expense to the Metropolitan Asylums Board and to the county and borough councils and their officers, all of whom appear to have *performed their various duties in a manner* worthy of high praise In his ninth annual report Mr Shirley Murphy gave an account of the occurrences of small pox in the course of that year Inasmuch as the epidemic extended far into the summer of 1902 it is not as yet possible to discuss completely the behaviour of the outbreak as a whole. Nevertheless, it is instructive to review the manner in which small pox became diffused throughout the metropolis in 1901, causing some 1700 cases in that year alone. As Mr *Shirley Murphy has devoted* considerable attention and no small portion of his space to this subject we propose to summarise very briefly *his account of it for* the information of our readers. By the help of statistical tables and a useful diagram the history of small pox in stay the spread of small pox, but powers should be given for the compulsory vaccination of every tramp who could not prove that he had been vaccinated within the past seven years The Local Government Board for Scotland intimates that during the period from Jan 1st to 15th inclusive only one case of small pox has been notified to them—viz , the the case of a seaman on board a ship which arrived at Glasgow on Jan 1st Several cases of small-pox have occurred in Nottingham and it is stated that four of the patients are totally unvaccinated.

THE DISTRIBUTION OF PLAGUE

THE medical officer of health of Cape Colony reports that for the week ending Dec 27th, 1902, 2 cases of plague were discovered at Port Elizabeth, the one being in a native male adult who was found dead on Dec. 24th and the other being that of a European male adult notified on Dec 26th At the end of the week 2 cases remained under treatment at the Plague Hospital at Port Elizabeth. The last preceding case of plague notified occurred on Dec 19th. No case of plague has been discovered or was under treatment in any other place in the Colony during the week in question As regards Hong Kong, a telegram from the Governor received at the Colonial Office on Jan 16th states that for the week ending Jan. 15th there had been 18 cases of bubonic plague and 10 deaths from the disease.

DANGEROUS GAS-HEATERS AND COAL-GAS POISONING

CARBON monoxide is rapidly becoming a modern terror, for undoubtedly the number of victims to carbon monoxide poisoning is decidedly on the increase Sometimes the gas occurs as a product of incomplete combustion owing to a defect in the gas heater, as was the case in the regrettable death of Mr Quintin Hogg in a bathroom at the Polytechnic Institute last week, and sometimes it reaches its victim through the escape of coal gas from a defective gas pendant. Two children lost their lives last week by this latter means there was no water in the seal of the chandelier and gas freely escaped into the room in which they were sleeping We unequivocally condemned this wretched gas appliance a long time ago Gas companies, we maintain, should be compelled to supply all their customers using gas stoves with printed directions as to their management, and it seems to us that the increasing proportion of carbon monoxide in coal gas calls for serious investigation

THE KING S SANATORIUM A NOVEL SCHEME

ONE of the schemes sent in for competition, which the author has permitted us to see, involved principles entirely at variance with the successful ones in its suggestions for treating tuberculous patients. The gist of it lay in an attempt to furnish the patients—who would be completely isolated, collectively and individually, within the sanatorium on the hillside—with a plentiful supply of air, fresh from the summit of a hill, of regulated temperature and moisture The air, for instance, would need drying when a cloud or heavy mist capped the hill top , it would require moistening and warming when easterly and north easterly winds prevailed, and toning down when too "shrewd" or frosty This scheme advised that the air (modified when necessary) should flow continuously up through the perforated floor of the patient's cubicle, rising evenly throughout the room, and should pass away through the perforated ceiling to a foul-air chamber, whence it would be drawn away to feed the flames at the destructor A great point in the scheme was the complete destruction by heat of all liquid, solid, and gaseous refuse The writer believes that his method of ventilation could be superseded by flooding the rooms with fresh air from the top and drawing it away from the bottom of the cubicle, a plan already successfully adopted in some places, he thinks that there should be a double foul air system in order to keep separate the ward and drainage ventilation and that all the patients' cubicles should face the front The author of the scheme has founded his plan upon a view that the treatment of weak, sensitive patients by the open air method will eventually break down in England. This, of course, is not accepted opinion, but undoubtedly it is necessary that we should remember that when we have placed a tuberculous person, regardless of his individual condition, in the open air, and not paid sufficient attention to the quality of that air, we may not have done our best for him or her.

THE INDEX MEDICUS SECOND SERIES.

THE Index Medicus, which was established in 1879 and discontinued in 1899, has now been resumed. The present publication, which is undertaken by the Carnegie Institution in Washington, will be known as Index Medicus, Second Series, Volume I , commencing in January, 1903 It consists of the titles in full of books, pamphlets theses, contributions to coöperative works, and original articles in journals, transactions of medical and scientific societies, and the like arranged under subject headings. On the completion of the volume an "Annual Index of Authors and Subjects" will be issued. The subject part of this annual index will be elaborately subdivided, the classification closely resembling that of the Index Catalogue of the Library of the Surgeon General s Office. The annual subscription, payable in advance, is $5, or 25s All communications relating to subscriptions should be addressed Carnegie Institution, Washington, D C Letters relating to the editorial department should be addressed Editors, Index Medicus, Washington, D C

STRONG MEASURES AGAINST SMALL-POX AT PHILADELPHIA

THE city of Philadelphia seems constantly in difficulties. When there is no epidemic of typhoid fever then small pox breaks out, and when small pox ceases typhoid fever returns Now both these diseases have come together and this in spite of an improved water supply and energetic measures to vaccinate the whole population Indeed, small pox has broken out among those engaged as it were in the prevention of typhoid fever There are some 500 negro labourers employed at a filtration conduit and filter beds At shaft No 8 one negro was seized with small pox and removed at once to the hospital, but at almost the same time two other cases occurred at shaft No 6 The huts which these patients occupied have been quarantined" and their inmates—there are generally ten negroes in each hut—are kept prisoners The police are stationed round the huts to prevent all intercourse with their inhabitants who are thus kept in idleness in a confined space waiting for small pox to attack them or for their daily allowance of food to be handed to them through the windows of their huts We are now told that all the coloured men are to be vaccinated, which assuredly is a better precaution. Ten policemen are told off to watch each hut, and this display of force has naturally helped to spread a panic among the labourers engaged at the waterworks which it is anticipated will be the means of preventing typhoid fever by giving the inhabitants of Philadelphia pure water to drink Throughout the town the police have been paying house to house visits to ascertain how many inhabitants have not been vaccinated within the last five years Arrangements are made for the immediate vaccination or revaccination of such persons. These precautions are useful, but they should be supplemented by measures to prevent overcrowding and to remedy structural e opposition to vaccination mainly associated itself with fects of administration of the Vaccination Acts. He held rongly the opinion that by a thorough investigation of the fects of the machinery of vaccination legislation could be ost safely promoted

Dr J C McVail urged the importance of the revaccination children before leaving school. When a child was proaching 12 years of age the duty should be impressed pon the parent of seeing that the child was protected gainst small pox before entering further on his or her reer He ventured to think that the President of the ocal Government Board, who had abolished rabies in this untry, had a great opportunity of conferring an enormous oon on the country in connexion with an infinitely more nportant subject—namely, small pox.

Mr Devitt, representing commerce, gave instances of the eavy loss which had fallen upon ship-owners owing to a ngle case of small pox having occurred on board a ship

Mr E. Debenham, representing the clothing, furnishing, nd allied trades presented a petition signed by firms mploying about 30,000 persons in favour of revaccination.

Dr Adler, the Chief Rabbi, speaking of the strenuous fforts which were made to secure the revaccination of all ewish children attending voluntary and board schools, nd he was certain that no case of small pox occurred mong the children attending three board schools in e East-end, which had an aggregate of over 2000 ames on the register The managers secured the help f the public vaccinator who was good enough to ttend twice a week at an institution near the schools. he confidence reposed by the parents in the managers and eachers was so great that they brought or sent their children n large numbers, so that at least 75 per cent. of scholars ver eight years of age were vaccinated In fact so anxious ere the parents that the children should be protected that n many cases they brought children below the age at which evaccination was deemed needful and begged that they hould be vaccinated. He laid special stress upon the fact hat it was of the utmost importance that children should be evaccinated while at school before they attained the age of 2 or 13 years

Alderman Menlove chairman of the Liverpool Health Committee, said that power should be given to health uthorities to vaccinate or to revaccinate anyone who had ome in contact with a case of small pox.

Mr R. Brudenell Carter said he had been asked to say a few words on the question of cost in relation to the prevention of small pox. They naturally looked to Government to protect the property as well as the persons of its subjects, nd the property of the people of this country had been njuriously affected by small pox epidemics in an amazing manner If they took London alone, the expenditure of the Metropolitan Asylums Board in the recent epidemic was estimated to have been at least half a million sterling that sum not including the expense to which the different boroughs of the metropolis were put for the conveyance away of the different cases within their limits, or the disinfection of the houses in which small pox had occurred The hospital ships on the Thames cost something like £15 000 a year Yet this expenditure of money large as it was, did not equal the loss which was inflicted on the various localities by the disturbance of trade and of the ordinary events of life which an epidemic of small pox invariably caused. The Government ought to take into account not only individual loss but the great loss in national wealth due to disease.

Dr T D Acland urged the necessity for a liberal supply of the glycerinated lymph.

Sir William Broadbent, Bart., K.C.V.O., said that he thought the difficulties of the conscientious objector would be lessened by pressure of public opinion as expressed by the great employers of labour

Dr J G Glover said that Mr Barnardo had had under his care in Stepney between 6000 and 7000 children during the 18 months of the recent epidemic and that these children having been vaccinated, there had not been one case of small pox among them.

Copies of the following declaration were handed to Mr Long —

> Believing that in vaccination and revaccination we possess the best protection against epidemic small pox I should heartily welcome legislation making revaccination at school age obligatory on all but the children of conscientious objectors or those who may be for a time excused on the ground of ill health.

The signatories included Sir Thomas Dyke Acland, Sir Thomas Barlow, Mr T J Barnardo, Mr H. Rider Haggard, Professor D MacAlister, Sir William Turner, Sir John Williams, the head masters of many large public schools, the head mistresses of important public girls' schools, the heads or honorary secretaries of colleges for women, the Lord Mayors and mayors of a number of important cities and boroughs, the representatives of a number of large employers of labour and of many ship-owners and owners of lines of steamers, several firms of ship builders, the chairman and secretary of Lloyd's Registry, City solicitors, and many others

Mr Long said that it was unnecessary for him to refute either the allegations or the arguments which had been advanced by the speakers. No one, he need hardly say, in the office of the Local Government Board would attempt to dispute either the assertions which had been made in support of vaccination or the gravity which had been rightly attached to the successful performance of that operation throughout the country At the Local Government Board they had a constant and growing experience of the advantages of vaccination, and the only wonder they felt at all was that it should be necessary at this period of the world's history for a great deputation so representative in character and gathering its members from all parts of the country to come there in order to support that which they, in that office at all events, believed ought to receive the unqualified support of every intelligent person. He hoped that that remark would not be misunderstood by those who did not believe in vaccination. He did not desire to say anything which would offend the susceptibilities of those who believed that vaccination was wrong, but he felt bound to say that the more he had studied the question the more difficult he found it to understand how anyone could refuse to give hearty support to that which he believed to be one of the greatest instruments of preventive medicine that had ever been given to the world. Germany had practically eliminated the disease altogether and the effect of vaccination in India was well worthy of study It was a common remark often heard from people of a certain age who said that in their young days it was quite an every day occurrence to meet men and women one after another in the daily avocations of life who were disfigured by small pox whereas now it was the exception What was the reason? It was not a process of nature which had been going on of itself without any assistance from science. It was not an accident, but it was due to some cause. What was the cause? Those who did not believe in vaccination said that the proper remedy for small pox was isolation. Isolation was, no doubt, an excellent thing, but could any man in his senses believe that if in this country nothing but a process of isolation had been adopted the remarkable change in the condition of the people which had occurred since the days when small pox was a common disease would have been brought about? It was surely not unfair for the adherents of vaccination to believe that this remarkable and beneficent change in the health of the people was due to revaccination in spite of all the obstacles which in this country had been placed in its way They must not expect him on that occasion to state in any definite terms what the intentions of the Government were. In the first place, it was not usual to do that on such occasions, and in the second place, even if it were usual so active were the opponents of vaccination that he thought it would be very undesirable to make them a present of the Government proposals beforehand, because then they would get themselves into line of battle much earlier than was desirable He could not help regretting that a great society like the Imperial Vaccination League had not come into existence many years ago and become as active in the constituencies of the country as the Anti-Vaccination League had been. Such a society would have been able to render invaluable assistance to Parliamentary candidates who were pressed on that question by those who were hostile to vaccination and told harrowing tales of the suffering, death, and misery which had resulted from vaccination. He hoped that that deputation was evidence of the fact that they had put their hands to the plough and that they did not mean to turn back until the work was done. The strongest Government could not carry legislation in the teeth of strong public opposition, but he believed that the great majority of the country were with those who held the views of the deputation and that if the facts were made known and the evidence was only put before the people of the country there would be a much larger majority in favour of vaccination If the vaccination laws were going to be amended so as to make them effective it was necessary that an influential body the metropolis is traced through a long series of years both as regards incidence and mortality We note that until the recent outbreak the disease had not been seriously prevalent amongst us since 1893, in which year 2815 cases were reported, whilst the total number notified in 1901 did not exceed 1700 But although the attack incidence during the latter year was considerably lower than that of the former, the mortality in proportion to population was nevertheless considerably higher, the small pox death rates being 0 040 per 1000 in 1893 and 0 051 per 1000 in 1901 Until the history of the recent epidemic can be considered as a whole it is perhaps unsafe to attempt an explanation of this remarkable difference, age distribution may have had something to do with it but it is far from improbable that it is due mainly to differences in the degree of vaccinal protection against fatal small pox possessed by the population generally at the respective periods Very early in his account of the recent outbreak Mr Shirley Murphy gives prominence to the fact that in a relatively large number of instances cases of illness were erroneously notified as small pox and were actually removed from their homes to hospital under the mistaken impression that they were suffering from that disease. As a consequence the persons referred to were unnecessarily exposed to infection and in this way further diffusion of the disease is not unlikely to have occurred We have before drawn the attention of our readers to the fact that in recent years, in consequence of the disappearance from amongst us of certain formerly common infectious diseases—typhus fever for example—medical practitioners enjoy at the present day fewer opportunities of becoming familiar, clinically, with these diseases, and we see in this fact a danger to the public health of our crowded districts against which it behoves us as a profession to be on our guard. This is notably the case with regard to small pox also, but we certainly were not prepared for the statement, which we have on the authority of the county medical officer of health, that in so large a proportion as 13 3 per cent of the notified cases the diagnosis of small pox had turned out on investigation to be incorrect.

It is gratifying in these circumstances to place on record the admirable temper in which the authorities, under Mr Shirley Murphy's guidance, dealt with this unsatisfactory state of things There is no doubt that in certain cases there exists a real difficulty in distinguishing variola from varicella, especially when as is frequently the case, the former disease is modified by vaccination. Recognising this difficulty, and with praiseworthy determination to meet it, several of the metropolitan vestries, and ultimately the County Council, agreed to schedule chicken pox among the infectious diseases, notification of which should be for a time required under the Local Act. The last-mentioned authority further made arrangements by which the services of medical men specially familiar with small pox were made generally available in obscure cases for purposes of diagnosis There can be no doubt whatever that the prompt adoption of these prudent expedients has had the effect of bringing to an early close an epidemic which at one time threatened to assume unmanageable proportions. The compulsory notification of chicken pox has been turned to account statistically by Mr Shirley Murphy to show the age distribution of chicken pox and incidentally its relation in time and place to the prevalence of the graver disease From the year 1901 up to the present time the county medical officer of health has published week by week particulars of the local distribution of *varicella* in each of the London boroughs, and also of the notified attacks of this malady at the various ages from early infancy onwards This information, which is now available in England for the first time, will, if we mistake not, be shown at no distant date to possess considerable scientific importance from the point of view of preventive medicine.

The history of recent metropolitan small pox diffusion from initial attacks is given with sufficient fulness in Mr Shirley Murphy's report, the details do not differ essentially from those which have been experienced in previous epidemics elsewhere, whenever record has been preserved with equal minuteness

It is the old story of unrecognised and unsuspected cases obtaining entrance into elementary schools common lodging houses, and even into workhouses and into the wards of general hospitals Mr Shirley Murphy gives an account of the steps taken by the medical officers of health of infected districts with the object of limiting the spread of the disease In some districts these included an inspection of the children in schools, with a view of ascertaining whether or not they had been vaccinated. Some of the local medical officers of health show in their reports the proportion of children whose parents posed as "conscientious objectors" to vaccination and also the proportion of children found on examination to be unvaccinated. Thus, in Greenwich between 7000 and 8000 children were inspected, of whom less than 10 per cent. exhibited satisfactory marks of vaccination and the parents of more than 5000 of these refused to submit their children to the operation

Throughout London generally there was during the epidemic, and probably from fear of it, considerable resort both to vaccination and to revaccination. In Islington 1866 children were vaccinated in consequence of the action of the authorities, and in Westminster nearly 10,000 were revaccinated by the public vaccinators alone, leaving a probably larger number who resorted for protection to their private medical attendants.

THE IMPERIAL VACCINATION LEAGUE.

DEPUTATION TO THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD

AN influential deputation from the Imperial Vaccination League was received by Mr Walter Long, the President of the Local Government Board, on Jan 14th.

At the commencement of the proceedings Sir JAMES CRICHTON BROWNE read a letter from the Duke of Northumberland, President of the League, who was unavoidably absent, in which His Grace strongly urged careful administration of the present Acts relating to small pox and their extension and improvement

Sir WILLIAM CHURCH, Bart, K.C B, who introduced the deputation, pointed out that the Imperial Vaccination League was not a medical association, naturally a large number of medical men were included among its members, but the main strength of the Imperial Vaccination League consisted in the support which it received from the general public. The points which the League particularly desired to bring to Mr. Long's notice were these the necessity for efficient infant vaccination and for revaccination at a later period of life and the removal of the administration of the Act from the guardians of the poor to some other body They also desired to draw attention to the very large expense which was entailed upon districts and upon the country at large in the event of an epidemic of small pox either taking place or being feared. They also wished to draw attention to the necessity for the making of arrangements by which a larger supply of lymph prepared under efficient observation might be obtained

Professor CLIFFORD ALLBUTT, M.D, after referring to the dislocation of the business of the country which a small pox epidemic caused, said that the deputation consisted largely of men of business—ship-owners, bankers, presidents of chambers of commerce, and large employers of labour It was they who came there that day to explain that the beneficent effect of vaccination had not been carried far enough. The time had come when others than medical men were pressing upon the Government that the Vaccination Acts ought to be revised Statistics had recently been shown to him he said, which indicated that among the population of Berlin small pox had virtually ceased. The sporadic cases which occurred in Berlin had come virtually from other countries If these were extracted from the small pox statistics of Berlin small pox might be said to be non existent in that city If children were revaccinated at the ages of 10 or 12 years there was a probability that the protection which vaccination afforded would extend to the end of their lives and he urged that parents should be helped to carry out such needful protection to their children. He welcomed the conscientious objector who had caused them to examine their arguments, to revise their methods of research, and had kept them awake. They had not the smallest desire to interfere in any way with those who had conscientious objections on that matter In the face of criticism, however it was absolutely necessary that lymph should be beyond suspicion

Dr F T BOND, secretary to the Jenner Society, said that

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY meeting of the Council was held on an 15th, Sir HENRY G HOWSE, the President, being in he chair

Mr. Clinton T Dent was introduced and having made a declaration in the terms of the oath prescribed by the Charter of 1800 was admitted a member of the Court of Examiners

The best thanks of the Council were given to Mr. Bolton Glanvill Corney for his gift to the museum of 16 skulls of members of the Melanesian, Malayo-Polynesian and hybrid Fijian) races

The PRESIDENT reported the award of the Sir Gilbert Blane medal to Christopher Louis White Bunton M.B., B.Ch. R.U I. Surgeon R.N, H.M.S *Forte*, 1901, and John Falconer Hall, M.B., C M. Aberd. Staff-Surgeon R.N, H.M Naval Brigade in North China, 1900.

A letter was read from Mr. Frederick Canton resigning his seat on the Board of Examiners in Dental Surgery —The PRESIDENT stated that the vacancy thus occasioned would be filled at the ordinary meeting of the Council in March. (Applications for the post must be sent in before Feb. 7th)

A letter was read from the Secretary of the University of Birmingham reporting the expiration on Jan. 1st, 1903, of the term of office of Sir Henry G Howse on the court of governors of the university The Council recommended Sir Henry G Howse for re-election

A letter was read from Mr Reginald Harrison reporting his attendance as the delegate of the College at the Medical Congress at Cairo The best thanks of the Council were given to Mr Harrison for representing the College at the Congress.

A letter was read from the Foreign Office inclosing a copy of a despatch from Lord Cromer to Lord Lansdowne expressing the appreciation felt by the Khedive and the Egyptian authorities at the action taken by the College in sending Mr Harrison to the Cairo Congress and to inspect the Cairo School of Medicine.

A letter was read from Dr H. P Keatinge, director of the Cairo School of Medicine, reporting that he had furnished Mr. Harrison with all the information in his power respecting the curriculum of the school, thanking the Council for the interest taken by it in the institution, and expressing the hope that the result of Mr Harrison's investigations might lead to the recognition of its teaching

THE PREVENTION OF CONSUMPTION AND OTHER FORMS OF TUBERCULOSIS

RECOMMENDATIONS WITH REGARD TO PROPHYLAXIS.

AT a meeting of the council of the National Association for the Prevention of Consumption and other Forms of Tuberculosis held on Jan. 12th, Sir WILLIAM H. BROADBENT, Bart., K.C.V O being in the chair, the motions printed below were passed. The attention of the council having been called to the fact that notwithstanding the numerous notices against spitting which have been placed in various railway carriages, tramcars, and places of public resort, this disagreeable and dangerous habit still continues and also in view of the fact that spitting on the cars of certain tramway companies and in covered places of public resort in the county of Glamorgan has already been made a penal offence, it was decided that some further action was called for The following motion was therefore proposed by Mr MALCOLM A. MORRIS seconded by Dr. L. A. WEATHERLY supported by Dr. ARTHUR RANSOME, and carried unanimously —

> That spitting on the floors of public buildings, on platforms, corridors, staircases, and public carriages or passenger boats or in any covered place or public resort should be forbidden by law

The council at the same meeting also resolved —

> That the council of the National Association for the Prevention of Consumption, having read the report of the Tuberculous Committee of the Medico-Psychological Association of Great Britain are of opinion that the suggestions therein expressed are most valuable, and they urge the Commissioners in Lunacy to do their utmost to get the committees of the county and borough asylums to carry these suggestions into effect

The attention of the council has also been called to the report of a departmental committee on the ventilation of factories and workshops, 1902 (Blue-book, Cd. 1302) The chief recommendation in the report is (p. 5) that such a standard of ventilation should be prescribed for all classes of factories and workshops not otherwise dealt with The proportion of carbonic acid in the air at about the breathing level and away from the immediate influence of any special source of contamination shall not rise during daylight or after dark when only electric light is used beyond 12 volumes of carbonic acid per 10 000 of air, and that when gas or oil is used for lighting the proportion shall not exceed 20 volumes after dark or before the first hour of daylight ' The council of the association understands that, in accordance with the views of a previous committee, an Act was passed in 1897 fixing the standard of nine volumes of carbonic acid in all humidified cotton cloth factories and that this Act had been very successful in improving the condition of the workers in these factories.

> The council therefore beg to express their opinion that the newly suggested standard of ventilation should not be adopted by the Government as it would probably prove detrimental to the public health and would tend to increase the prevalence of tuberculous diseases.

SWANSEA.

A meeting convened by the Mayor of Swansea and Sir John Llewelyn (president of the Swansea Charity Organisation Society) was held at the town hall, Swansea, on Dec. 22nd, 1902, to consider the question of establishing a sanatorium for consumptive patients at Swansea.—The Mayor referred to the recent formation of a Swansea branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis and said that there were two alternatives before them—namely, whether they would apply to the county council to erect a sanatorium for that district or would themselves endeavour to raise public subscriptions. He thought that there was a general feeling that the provision should fall on the county council.—Sir John Llewelyn said that in his opinion they should go to a larger area than the borough of Swansea for the necessary capital if they depended upon voluntary subscriptions.—Mr J A. Rawlings M.R.C.S. Eng, suggested that they should establish a sanatorium for consumptives in connexion with, or as a wing of, the convalescent home now being built in connexion with the Swansea Hospital. He thought that the Swansea corporation might be willing to contribute £1000 towards such a scheme. The disease would not be infectious in a proper sanatorium.—Councillor R. Dommett said that the Swansea Trades Council was strongly of opinion that the proposed institution should be supported by the corporation and he proposed a motion as follows —

> That this meeting is of opinion that a convalescent home for consumptive cures should be provided by the Swansea corporation and maintained out of the rates under the powers conferred by the Public Health Act 1875.

Sir John Llewelyn seconded and the motion was adopted.—A deputation to wait on the corporation was appointed from amongst those present.—In reference to this aspect of the matter it may be stated that the corporation has for years refused to build a permanent hospital for the isolation of cases of infectious disease although repeatedly urged to do so by the medical officer of health, Mr Ebenezer Davies, and although the buildings which have served the town during the recent epidemic of small pox are anything but creditable, so that it will be interesting to see what action will be taken with regard to this latest proposal

CUMBERLAND

The work of providing a tuberculosis sanatorium for the county of Cumberland is being actively carried on and the executive committee has issued a public appeal which is signed by the Bishop of Carlisle as president, as well as by the honorary treasurer and secretary In this appeal the committee states that it has collected funds and purchased what is pronounced by experts to be one of the most suitable sites in England on the southern flank of Blencathra. Sheltered from winds facing the sun, with a good water-supply and exhilarating air, it is at the same time centrally situated and reached easily from west or east. The committee has also arranged for the planting of shelter-belts of fir and larch and for the converting of the adjacent farmhouse into an administrative building with dining-hall attached. From £3000 to £4000 must yet be raised before the erection of the sanatorium can be undertaken. The actual inclusive cost of each patient per week like the Imperial Vaccination League should bring to bear upon the people the knowledge and experience of its members. The first and most important of the proposals made by the deputation was whether the existing authority should be continued The history of our local government in England was a very remarkable one. Fresh powers had been created by Parliament and had been handed over to existing authorities who were not particularly adapted to the work of carrying them out. Could anything be more inconsistent with the proper functions of a board of guardians than that they should be charged with the general duty of vaccinating the people in their neighbourhood? What had vaccination against a terrible disease to do with the proper maintenance of the paupers? The guardians had done their best very often and very often the efficient administration of the Poor law had been interfered with by the agitation got up in connexion with vaccination at the time of the election of the guardians He believed that the proper line to adopt in reform of local government was that of centralising in the great central bodies of the country, as far as they could, those special parts of the government which had special application to the whole area and not special application to any parts of the area, therefore he inclined towards making the county councils and the borough councils the authorities in future With regard to revaccination he agreed with the remark made by Dr J C McVail and emphasised by him in a very interesting article which he had had the advantage of reading within the last day or two, that primary vaccination of itself was really almost a farce—to vaccinate the children and then to believe that everything had been done that was necessary in order to secure the proper effects of vaccination was almost a farce and was really almost a deception It would be a very great advantage if a practicable scheme of revaccination during adolescence or later life could be devised. Statistics were widely circulated by the opponents of vaccination in which allegations were frequently made that people had died from small pox who had been vaccinated, but in those statistics the period of lives at which these persons had been vaccinated was not stated, or whether they had ever been revaccinated, or whether it were not the fact that it was because they had only been vaccinated some 20 or 30 years before and had not been revaccinated that they had died from small pox. Vaccination in infancy, unless it were repeated at proper intervals, was not a certain safeguard Vaccination reduced the virulence of small pox, lessened the risk of infection, and if it was repeated at proper intervals it afforded a great safeguard against the contraction of the disease. There were those who would still say that vaccination was no remedy, and that the attempt to spread vaccination was to do that which was wrong and antagonistic to the liberties and the privileges of the people. He stood aghast in the face of statements of that kind. He could not understand why it was that a certain section of the community took so strong a view about the dangers of vaccination. Recently he had read an article in The Lancet[1] in which the hope was expressed that a Bill of a non-contentious nature dealing with vaccination might be introduced into Parliament. He was very doubtful whether the ingenuity, even of the Local Government Board, could devise a Bill which would be so regarded by the opponents of vaccination. With regard to the question of lymph, that was a very difficult question, and at present, although they had largely increased their vaccine establishment, it would be impossible to undertake to supply that lymph generally to the whole country He agreed that if vaccination was to be made general the supply of lymph should be of the best possible description, but he thought that they should be satisfied that the commercial lymph was unsatisfactory before they attempted to embark on so large a business as the supply by the Government of lymph for general use. That was a question he preferred to reserve for more careful consideration, because, naturally, it would involve a discussion between the Board and the Treasury and was not one on which he could now say what his final view would be He had tried to indicate in very general terms what his views were as Minister responsible there. He had not had any opportunity of consulting his colleagues, but he had tried to indicate what would be the general principles that would guide him in this matter Of this the deputation might rest assured, that they would do nothing at the Local Government Board which would be calculated in any way to lessen what they believed to be one of the greatest benefits enjoyed by this country—the general adoption throughout the country of vaccination as a preventive against one of the most terrible of our diseases

Sir James Crichton Browne briefly thanked Mr. Long, and the proceedings terminated.

Looking Back.

FROM

THE LANCET, *SATURDAY, JAN* 22, 1825.

REVIEWS FROM THE WEST

Under this title shall be noticed, from time to time, everything Medical coming within our reach, remarkable for stupidity or distinguished by excellence Nothing, destitute of one of these two qualities shall arrest our attention Mediocrity only, therefore, shall escape our vigilance, because from this negative, neither-one-way-or other, sort of thing, so prevalent at the present moment, there is no danger to be apprehended, or any advantage to be derived. This nondescript species of composition, in which the elements of good and evil are so happily blended that, like certain chemical compounds, every trace of the original constituents is lost in the neutral insipidity of the product, seems to us to be totally unworthy of observation. Our critical barometer admits of only two degrees—zero, and the boiling point, to one or other of these signs shall be referred whatever works we review, and on the same principle that we are told to read history, to be admonished by error and instructed by acts of prudence, we shall fearlessly expose absurdity and judiciously point out excellence for imitation. In no other form can we think that criticism may be rendered conducive to the interests of a science the professors of which should ever recollect, that, "to do good and to avoid evil" ought to be their motto, and the object of their lives.

The *Times* of Jan 19th, 1903, has the following interesting excerpt from its issue of Jan 19th, 1803 —

Extermination of the Small Pox.

London, Jan. 10 18

The invaluable Discovery of Dr JENNER for the Extermination of the Small Pox, having undergone the most rigorous investigation and received the sanction of Parliament a Meeting will be held at the London Tavern, Bishopsgate-street on Wednesday the 19th instant, at 12 o clock to consider of the best means of carrying the same into effect when the company of every Gentleman disposed to concur in this laudable Undertaking is earnestly requested The Chair will be taken by the Lord Mayor, precisely at one o clock.

our, and three in the three preceding weeks, increased again o four last week. The deaths from measles, which had een seven, nine, and two in the three preceding weeks, ose again last week to three. The 218 deaths in Dublin last week included 38 of children under one year of age and 7 of persons aged 60 years and upwards, the deaths of nfants were slightly fewer than those recorded in the preceding week, while those of elderly persons showed a considerable excess; 12 inquest cases and seven deaths from violence were registered, and 87, or 40 per cent., of the deaths occurred in public institutions. The causes of 11, or more than 5 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Sidney H. Carter retires on retired pay. Dated Jan. 17th, 1903.

Lieutenant-Colonel D. F. Franklin has embarked for India. Lieutenant-Colonel W. Dick is ordered to proceed to the Straits Settlements. Major J. B. Wilson joins at Woolwich.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among the officers of the Indian Medical Service made by the Government of India:—To be Surgeon General, Bombay Establishment: Colonel William McConaghy (dated Oct. 30th, 1902). To be Colonel, Bengal Establishment: Lieutenant-Colonel Henry Hamilton, retired. Dated Oct. 1st, 1902. Majors to be Lieutenant Colonels (dated Sept. 30th, 1902), Bengal Establishment: Albert William Denis Leahy and Richard Rose Weir. Madras Establishment: Robert Evans Stuart Davis and William Henry Neilson. Bombay Establishment: William Henry Burke and John Crimmin, C.I.E., V.C.

The King has approved of the retirement from the service of the undermentioned officers:—Bengal Establishment: Colonel Geoffrey Craythorne Hall (dated Nov. 1st, 1902), Lieutenant-Colonel Joshua Duke (dated Nov. 1st, 1902), and Lieutenant-Colonel William Edwin Griffiths (dated Jan. 6th, 1903). Madras Establishment: Lieutenant-Colonel Henry FitzLawrence Plunkett French Esmonde-White (dated Dec. 28th, 1902). Bombay Establishment: Surgeon General George Bainbridge (dated Oct. 30th, 1903) and Lieutenant-Colonel Henry Pruce Jervis (dated Nov. 27th, 1903).

The India Office publishes the following list of candidates for the Indian Medical Service who were successful at the competitive examinations held in London on Jan. 17th and following days:—

	Marks		Marks
C. S. Parker, M.B. Lond.	3413	E. C. Taylor, M.B., B.Ch. Cantab.	2890
P. N. White, M.B. Lond.	3063	D. P. Goll, M.B., B.Ch. Edin.	2505
T. C. Rutherfoord, M.B., B.S. Durh.	3037	H. C. Keates, M.B., B.S. Lond.	2330
D. Heron, M.B., B.Ch. Edin.	3018	R. A. Needham, M.B., B.S. Vict.	2327
L. Reynolds, B.Ch. Cantab.	2937	J. Kirkwood, M.B., B.Ch. Edin.	2312
H. H. Broome, M.B., B.Ch. Edin.	2930	A. Whitmore, M.B., B.Ch. Cantab.	2282
C. G. Seymour, M.R.C.S., L.R.C.P. Lond.	2930		

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Ayrshire and Galloway: Surgeon Lieutenant T. Harper to be Surgeon-Captain. Dated Jan. 17th, 1903. 1st Cheshire and Carnarvonshire: Surgeon Lieutenant T. G. Lusk to be Surgeon Captain. Dated Jan. 17th, 1903.

Submarine Miners: The Tyne Division: Surgeon-Captain W. H. Brown to be Surgeon-Major. Dated Jan. 17th, 1903.

Rifle: 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: Peter Mackellar Dewar to be Surgeon Lieutenant. Dated Jan. 17th, 1902. 1st Dumbartonshire: The undermentioned officer resigns his commission:—Surgeon-Captain T. J. Burton. Dated Jan. 17th, 1903.

THE UNION JACK CLUB.

A scheme for founding a club for the United Services is, we are glad to say, to be carried out and a building is shortly to be erected at a cost of £50,000 in the vicinity of Waterloo Station to act as a club for the use of our soldiers and sailors. The idea is to provide a building available for all belonging to the Imperial Forces where they can obtain comfortable beds, good food, and wholesome recreation at moderate rates. This strikes us as a very good idea and we do not think that a more suitable or better site than that proposed could have been chosen for the purpose. Apart from the obvious hygienic and economical advantages offered by such an institution everything should be done nowadays to render the public services attractive to intending soldiers and sailors. The plans of the building allow for 400 bedrooms, a restaurant, smoking rooms, billiard rooms, reading room, and other club accommodation. Although the club is in no way started under official auspices it has the warm approval of the Admiralty and War Office.

"Audi alteram partem."

THE RISE OF BLOOD PRESSURE IN LATER LIFE.

To the Editors of THE LANCET.

SIRS,—I much regret that I was unable to be present at the reading and discussion of Professor T. Clifford Allbutt's paper brought before the Royal Medical and Chirurgical Society, which is reported in THE LANCET of Jan. 17th, p. 170. There are one or two points on which with your permission I should like to comment. Doubtless Professor Allbutt's remark with regard to fatalism in medicine begotten in the post-mortem room is of historic value, but it has ceased to be applicable for many years, and I think even at the present time there are valuable lessons to be learned in that gloomy but interesting chamber, and especially in two directions—viz., (1) lessons of humility as well as greater exactness in diagnosis which every clinical physician who attends there must have learned and which those still in student life would do well to take more to heart; and (2) a useful examination into what I may in brief call "collateral pathology," an examination into all the compensatory, reparative, and substitution processes that may be discerned amidst the "wreckage" in the dead body, will teach us much and will enable us to appreciate those processes of repair and possibilities of compensation which in clinical medicine enter so largely into both diagnosis and prognosis. I regret, therefore, that Professor Allbutt of all men should say anything in discouragement of post-mortem work.

Whilst generally agreeing with the views so interestingly put by Professor Allbutt on the conditions affecting blood pressure, there are some points with regard to its mechanism upon which I should have ventured to remark. Professor Allbutt tells us that the two antecedent conditions upon which blood pressure must depend (ventricular force and valve competency being understood) are diminution of the calibre of the vessels and increased viscosity of the blood. Whilst he, I think rightly, expresses doubt as to narrowing of the vessels being present with sufficient uniformity in arterial degeneration to cause rise in blood pressure and consequent hypertrophy of heart, he, on the other hand, maintains a tantalising silence with regard to "viscosity of blood," as to the nature of which one would much have desired information.

Professor Allbutt only makes a passing reference to loss of elasticity in the vessels as concerned in the altered conditions of circulation—viz., that it is not proved to have any effect with regard to their capacity. Now it seems to me that loss of elasticity in degenerate vessels is a most important deprivation which increases the burden of the heart in maintaining circulation. The other factor which may precede, and often attends, degeneration is arterial contraction.

We cannot, of course, speak of vessel elasticity as a force in aid of circulation, but it is a most important factor which by perpetuating, in conjunction with competent aortic valves, the ventricular force helps to maintain the blood current. Deprived of elasticity as in the leathery vessels spoken of by Professor Allbutt, the vessels give a dead resistance to the blood movement which causes the waste of much cardiac force and tends to a low blood pressure and at the same time to cardiac hypertrophy. Arterial contraction is, in morbid degrees with which we are now alone concerned, also an opposing force to the blood current. Its full consideration would be a thesis of itself. I would regard it as in part a reaction to the toxic influence will be 30*s* The committee asks young and old, rich and poor, to coöperate in this work of mercy Contributions should be sent to the treasurer, Mr W L R. Crowder, jun., of 4, Portland square, Carlisle.

BRISTOL.

At a meeting of the Bristol health committee held at the council house on Jan. 6th the medical officer of health (Dr D S Davies) stated that he was at present engaged in the preparation of a report relative to a letter from the guardians on the treatment of consumption Any notification of this disease that might be secured would be voluntary, as the Government was not prepared to assent to the inclusion of any form of tuberculosis in a compulsory notification scheme.—The Chairman (Mr F G Barnet) said that at the council meeting recently a resolution was unanimously adopted asking the committee to report on the subject of consumption hospitals and notification. He thought that if Dr Davies reported on the size and general upkeep of such a hospital as Bristol would require the report could be sent to each member of the committee and they could ask the board of guardians to meet them in committee and see what could be done —Mr Pembery said that the council had voted a large sum to the Winsley sanatorium and so much a year for the allocation to the city of several beds —Mr Pope replied that the accommodation at Winsley would go but a little way towards meeting Bristol's need.—The medical officer was eventually asked to report as the chairman had suggested.

AUSTRIA

A public meeting was held in Vienna on Jan. 5th for the purpose of forming an anti tuberculosis union in Austria. Count Lützow was elected president and nearly £5000 were subscribed.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 8487 births and 5072 deaths were registered during the week ending Jan. 17th. The annual rate of mortality in these towns, which had been 16 9, 20 0, and 18 5 per 1000 in the three preceding weeks, declined again last week to 17 5 per 1000 In London the death rate was 17 5 per 1000, and was equal to the average rate in the 75 other large towns. The lowest death rates in these towns were 5 3 in Hornsey 5 7 in King s Norton, 8 1 in Tottenham, 9 7 in Barrow in Furness, 9 9 in Bournemouth 10 0 in Rotherham, 10 1 in Burton on Trent, and 11 0 in Warrington , the highest rates were 21 7 in Birmingham 21 8 in Wigan, 22 3 in Stockport, 22 4 in Swansea, 23 5 in Ipswich, 23 7 in Norwich, 24 3 in West Bromwich 24 8 in Tynemouth, and 31 8 in Bootle. The 5072 deaths in these towns last week included 450 which were referred to the principal infectious diseases, against 494, 602, and 504 in the three preceding weeks , of these 450 deaths 130 resulted from measles, 105 from whooping cough, 69 from diphtheria, 57 from diarrhœa 52 from scarlet fever, 31 from "fever" (principally enteric), and six from small pox. No death from any of these diseases was registered last week in Southampton, Reading, King's Norton, Smethwick, Aston Manor, Wallasey, Rochdale, Middlesbrough, or Rhondda , in the other towns these principal infectious diseases caused the highest death rates in Hanley, Walsall, West Bromwich, Stockport, Manchester Salford, Preston, Tynemouth, and Swansea. The greatest proportional mortality from measles occurred in Wolverhampton, West Bromwich, Wigan, Manchester, Salford Hull, Tynemouth Newport (Mon), and Swansea , from scarlet fever in West Bromwich and St. Helens , from diphtheria in Coventry, Stockport, and Bury , from whooping cough in Hanley, Stockport and Preston , and from diarrhœa in Walsall, Burnley, and Swansea. The mortality from "fever" showed no marked excess in any of the large towns. The six fatal cases of small pox registered in these towns last week belonged respectively to London, Hanley, Liverpool, Bootle, Manchester, and Huddersfield. The number of small pox patients under treatment in the Metropolitan Asylums hospitals, which had declined from 21 to 10 on the four preceding Saturdays, had further decreased to five on Saturday, Jan. 17th , two new cases were admitted during last week, against one and four in the two preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2128, against 2523, 2378, and 2219 at the end of the three preceding weeks , 195 new cases were admitted during the week, against 205, 214, and 223 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 343, 415, and 354 in the three preceding weeks, further declined last week to 310, and were 249 below the corrected average number Influenza was returned as the primary cause of death in 34 cases last week, against 28, 37, and 39 in the three preceding weeks The causes of 75, or 1 5 per cent., of the deaths in the 76 large towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Croydon, West Ham, Leicester, Nottingham, Cardiff, and 40 other smaller towns , the largest proportions of uncertified deaths were registered in Birmingham Liverpool, Bootle, St. Helens, Sheffield, Middlesbrough, Sunderland, South Shields, and Gateshead

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 21 3, 21 6, and 22 6 per 1000 in the three preceding weeks, further rose to 23 4 per 1000 during the week ending Jan 17th, and was 5 9 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17 8 in Edinburgh and 19 8 in Dundee to 25 3 in Glasgow and 29 8 in Aberdeen The 766 deaths in these towns included 32 which were referred to whooping cough, 18 to diarrhœa, 12 to measles, six to diphtheria, five to scarlet fever, and three to "fever," but not one to small pox. In all 76 deaths resulted from these principal infectious diseases last week, against 59, 77, and 78 in the three preceding weeks. These 76 deaths were equal to an annual rate of 2 3 per 1000, which was 0 7 per 1000 above the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough, which had been 33 and 24 in the two preceding weeks, rose again last week to 32, of which 23 occurred in Glasgow, three in Edinburgh three in Leith, and two in Aberdeen The deaths from diarrhœa, which had been 14 and 22 in the two preceding weeks, declined again to 18 last week, and included six in Glasgow, four in Dundee, two in Edinburgh, two in Aberdeen, and two in Greenock The fatal cases of measles, which had risen from five to 15 in the four preceding weeks, decreased again last week to 12, of which five were registered in Edinburgh, five in Aberdeen, and two in Leith. The deaths from diphtheria, which had been 13 and seven in the two preceding weeks further declined to six last week, and included five in Glasgow The fatal cases of scarlet fever, which had been three in each of the three preceding weeks, increased last week to five, of which two occurred in Glasgow, where two of the three deaths from "fever" also were registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 193, 158, and 152 in the three preceding weeks, rose again last week to 174, but were slightly below the number in the corresponding period of last year The causes of 27, or nearly 4 per cent., of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had been 24 6, 29 4, and 26 8 per 1000 in the three preceding weeks, rose again to 30 0 per 1000 during the week ending Jan. 17th During the past four weeks the death rate has averaged 27 7 per 1000, the rates during the same period being 18 5 in London and 19 2 in Edinburgh. The 218 deaths of persons belonging to Dublin registered during the week under notice showed an increase of 23 over the number in the preceding week, and included 16 which were referred to the principal infectious diseases, against 21, 23 and 14 in the three preceding weeks , of these six resulted from "fever," four from diphtheria, three from measles, two from whooping-cough, and one from scarlet fever, but not one from either small pox or diarrhœa. These 16 deaths were equal to an annual rate of 2 2 per 1000, the death-rates last week from the same diseases being 1 5 in London and 1 9 in Edinburgh The deaths referred to different forms of "fever," which had been four, two, and two in the three preceding weeks, rose again last week to six. The fatal cases of diphtheria, which had been three, myself while in Calcutta on the Royal Society s Malaria mission examined 80 such *cases of malarial cachexia,* n none of these did we find parasites, pigmented cytes, *or an increase of the large mononuclear leuco-* Post mortem there was pigment in the organs but no parasites *It can serve no useful purpose to classify* cases with those in which there is an active infection para ites in the blood Those who are responsible for statistics, civil and military have at present no option them. They would as a whole, I think, welcome a ge which would give to the figures a more definite ning than they now bear

I am, Sirs, yours faithfully,
J W W STEPHENS
17th 1903 Lecturer Liverpool School of Tropical Medicine.

WEATHER AND SMALL-POX

To the Editors of THE LANCET.

RS,—Thinking that the subjoined fact taken from Mr liam *Digby's lately published* work, "Natural Law in estrial Phenomena" (William Hutchinson and Co), may rest your readers I venture to send it to you. The above or has given a full and remarkable account of Mr Hugh nents's investigations on "weather forecasting" for many rs past, and whilst treating of lunar cycles makes the follow statement ' The next lunar cycle in order is that of 130 rs. This cycle contains the lunar node cycle of 18 6 years seven times and is a multiple of the 10 and 13 years' ar cycles *The weather* of 1902 and of 1772 is so similar t there were ***small-pox epidemics*** in both years" (p 321)

I am, Sirs, yours faithfully,
n. 15th 1903. ALFRED HAVILAND

A DISCLAIMER

To the Editors of THE LANCET.

IRS,—*Some weeks since I received* a book of testimonials ating to a product known as "odol," and I was astounded see that one of *them purported* to have been given by me t once wrote to the proprietors pointing out that I had er given the *testimonial* in question, nor, in fact, pressed any opinion of my own about their product, and uesting that it should at once be cancelled I received in ly a courteous letter acknowledging that I had never given estimonial or *authorised* the use of my name in connon therewith and promising to take steps to prevent its ther publication.

n a copy of the book which reached me from the office t night the testimonial again appears, the proprietors parently considering that I ought to be satisfied with a y "erratum" in a corner of the last page. In order to clear self of any complicity in the matter I trust that you will w me to repudiate all responsibility in connexion with s unauthorised use of my name, an abuse which has drawn n me the notice of the Censors of the Royal College of ysicians of London. It is within my knowledge that at st one other testimonial therein contained has also been blished without authority

I am, Sirs, yours faithfully,
ALFRED S GUBB, M.D Paris.
ower-street W C Jan. 17th 1903

⁂ The proprietors of "odol" will, we trust, see the reme impropriety of the conduct imputed to them and ll take steps to remedy the mischief and to obviate its urrence.—ED L.

THE HUNTERIAN MUSEUM

To the Editors of THE LANCET

SIRS,—I would like to invite the attention of the museum mmittee to the growing practice of holding tutorial classes the Hunterian Museum, a practice which makes almost possible the study and research for which such a museum intended Sometimes I notice that the instruction or ther coaching, has no reference to the specimens, and the useum thus becomes a class-room for the unattached ammer As the various medical schools are equipped with useums for the purpose of elementary instruction I would k that the Hunterian Museum be reserved for silent study ly

I am, Sirs, yours faithfully,
Jan. 17th 1903. M.D LOND , F R.C S.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT)

The Great Coronation Durbar some of the Medical and Sanitary Arrangements —The Plague Mortality

IT is no small thing to make medical and sanitary arrangements for a camp containing 150,000 people and covering an area of nearly 40 square miles. Practically the whole of this vast undertaking is in the hands of a special staff, with Colonel C J Bamber, I.M.S , as administrative sanitary officer , Colonel H. B Thornhill I.S O , as executive sanitary officer , Major F Wyville Thomson, I.M S , as chief assistant administrative officer , and Captain C H. James, I.M S , as special plague officer The numerous camps, including the military are grouped into six sanitary circles, *each with its* sanitary inspector and large staff *of sweepers* There is a medical *officer in charge of each camp* , a *hospital* tent with staff has also been arranged for each camp For *infectious diseases, including* plague, there are four segregation hospitals. For ordinary illness provision is *made for treating* cases in *their* own tents by the medical officer in charge, but if serious there is the Civil *Hospital* in the city For natives there is a hospital of 50 beds in addition to the camp tent hospitals which also act as outdoor dispensaries. Those are very briefly the medical arrangements The water supply is partly from the water works of the city and partly from wells The latter have been utilised because many natives will not use pipe water The chief supply has been *distributed* from the water works in iron pipes This has amounted to nearly 2,000 000 gallons a day—about double the ordinary supply Running through the huge camp is a canal from the river Jumna which has been largely availed of for the purposes of watering the roads. The water from the works is pumped up to a reservoir on the "ridge," from which it is distributed throughout the camp at a fairly good pressure, standposts being very numerous The water supplied for drinking is, I am told, of satisfactory purity The wells have all been cleaned out and treated with permanganate of potash and each well has a guard of two men to prevent its being contaminated Bathing, except where special arrangements are made in tents, has to be done in the Jumna or canal and the washing of clothes is only permitted in the river The excreta are removed from the tents to iron receptacles, one of which is supplied for every 50 persons. The receptacles are carted some distance off and the night-soil is deposited in trenches. This is the general rule but some of the camps have arranged for trenching close at hand. Latrines are provided for servants and public urinals, consisting of a mat-screen surrounding a heap of sawdust or pulverised dry earth, are freely distributed. These latter have been found inoffensive, but the material *requires to be* stirred up from time to time. Waste water and other refuse from the kitchens are disposed of in absorption pits, *consisting* of holes dug in the ground and filled with broken bricks, and bath water from tents is thrown on grass plots or flower beds. It is not the individual details which are of interest but the vastness of the collective preparations and up to the present (Jan. 2nd) all the arrangements have worked exceedingly well, but the strain on the staff *during* the *present* busy week is tremendous.

I regret to have to record the death from appendicitis of Dr E C Pettifer one of the special plague medical officers in Calcutta He formerly practised in Essex, but *since 1897* has been doing plague work in India.

The mortality from plague throughout India *continues to* rise. For the week ending Dec 20th 14,203 deaths are recorded, compared with 13,415 in the *preceding* seven days and 9198 in the corresponding week last year The Bombay Presidency returns 7056 deaths , United Provinces, 1639 , the Punjab, 1734 , Mysore State, 871 , Hyderabad State, 641 , Madras Presidency 478 , Berar, 316 , Bombay City, 130 , Karachi, 16 , and Calcutta, 22. There is an increase in Madras, Bengal, and United Provinces but reduced numbers are returned for Bombay and the Punjab The epidemic, however, is spreading Plague has been officially declared at Jubbulpore and also for the first time in Lucknow In several important cities it is developing —viz., in Benares Allahabad, and Meerut. Inoculation for plague in the Punjab is to be recommenced during the second week in January at those places where the natives show a disposition to take advantage of it. Although there of that "viscosity of blood" spoken of by Professor Allbutt, which I take to be blood more or less charged with products of imperfect metabolism. But arterial contraction has also a more common cause, probably in the central nervous system. It is an intermittent condition that may long precede any definite cardio-vascular changes I doubt whether one meets with raised blood pressure in association with arterio sclerosis which is not due to associated arterial contraction and which cannot be relieved temporarily by a dose of a vaso-dilator drug or modified more permanently by other medicinal and dietetic treatment.

I am, Sirs, yours faithfully,

Wimpole-street Jan 17th 1903 R. DOUGLAS POWELL

RIGHT-HANDEDNESS AND LEFT-BRAINEDNESS

To the Editors of THE LANCET

SIRS,—I have no objections to make to Dr James More's communication on Right-handedness and Left brainedness in THE LANCET of Jan 17th p 200, except that it does not touch the point which most interests me It is true that my letter in THE LANCET of Dec 13th, 1902, p 1658, like all the others, was headed "Right-handedness and Left-brainedness" but neither of these subjects did I discuss, I did not, indeed, offer any speculations at all but dealt only with facts and common knowledge I maintained that in a large number of movements one could use only one hand or the other in a given way and therefore there was no such thing as ambidexterity in the sense in which many persons use the term. Dr More only alludes to the subject when he speaks of the weaver and calls him ambidextrous but does not inform us how the hands were used. I apprehend that, as usual, the two hands were employed for a common purpose and not that they were used in the same manner—which would have been purposeless—but mutually aiding each other by their own special action. I have no objection in using the term in this sense, that is, that the weaver was dextrous or skilled with both hands and not that he was doubly right-handed, although it is not usually employed in this sense for then a violin player would be the best example I know of an ambidextrous man, where each hand is educated for its own special movement.

I do not deny that when a person has lost his right arm he can learn to write in the usual manner with his left, but he does so only after a long time and effort as he is bringing into use quite another set of muscular movements. In the case of the screw, a left-handed workman acts with great disadvantage in having to use pronators for supinators, &c. Many children have a great difficulty in using different sets of muscles in playing the scale They easily enough accomplish it with the right hand, beginning with the thumb and proceeding outwards, but to accompany this with the left beginning with the little finger and proceeding inwards is often a difficult task. This in one sense is being ambidextrous

I think that ambidexterity is not intended to apply to the case where the left hand copies the right as happens in the left handed writer, nor does it apply to the pianoforte player, nor do I think it is ever used for the person who is skilled in the use of both hands for different purposes, as the weaver or violin player I think that it is generally understood to mean the case where a person can use equally well his left hand and his right for the same object If so he must employ the corresponding muscles with their similar nerve supply, the movements are necessarily different although the object to be obtained is the same An ambidextrous surgeon obtains an advantage in this by not moving his position, so does the ambidextrous waiter who carves the fowl without turning it round, and that the left-handed bowler goes out of the usual course is well known to the batsman. Would it be an advantage to educate the legs equally so that he could mount a horse as well on its right as on its left side?

I am, Sirs yours faithfully

Jan 20th 1903 SAMUEL WILKS.

CONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS

To the Editors of THE LANCET

SIRS,—I was much interested in reading the paper upon Congenital Hypertrophic Stenosis of the Pylorus, communicated by Dr E. Cautley and Mr C T Dent at a recent meeting of the Royal Medical and Chirurgical Society[1] In the discussion which followed the majority of the speakers, in referring to the etiology of this remarkable affection, favoured the view that the increased muscular tissue encircling the pylorus was due to spasm or abnormal innervation, while others considered the condition to be one of primary hyperplasia and not of hypertrophy For my own part I believe the arguments advanced by Dr Cautley and Mr Dent in favour of a primary hyperplasia to be convincing But there still remains the question, What is the cause of the primary hyperplasia?

My object in writing is to make a suggestion. In many of the mammalia the pylorus is provided with an excessive thickening of its muscular wall for reasons essential to the welfare of the animal and which need not now be discussed This muscular pyloric collar is well marked in the Bruta and in Vol III of the "Anatomy of the Vertebrates," by the late Professor Owen, there is on p 448 a drawing of the stomach of the great ant-eater which resembles so closely the condition found in so called congenital hypertrophic stenosis of the pylorus that I venture to suggest, while the etiology of this condition is "still in the nebulous regions of hypothesis," that the primary hyperplasia may be due to a reversion to an original type.

I am, Sirs, yours faithfully,

Liverpool Jan 15th 1903 R. W MURRAY

HOSPITAL FINANCE

To the Editors of THE LANCET

SIRS,—The Local Government Board states that it is advised that phthisis is a disease for which hospital provision may be provided at the cost of the rates, there are thus three common diseases—phthisis, enteric fever, and diphtheria—for which provision is made and of which cases, if admitted into general hospitals, are admitted to the exclusion of cases for which no provision is made, unless, that is, the infectious cases are paid for, nevertheless, these cases are admitted into general hospitals and in considerable number, and that for three reasons (1) they are too ill to be sent away, (2) they cannot be diagnosed with certainty and therefore cannot be certified, and (3) the physicians take much interest in such cases. It is stated that the Metropolitan Asylums Board, though ready enough to pay for cases when its own hospitals are full, is not willing at other times to do so, but it is difficult to see why the Board should refuse (if indeed it does refuse) to pay at any time for cases under No 1 or under No 2, for patients are not benefited by a long ambulance ride The financial importance of the matter will be seen from an example in one general hospital during one year among 3138 admissions there were 63 cases of phthisis, 90 cases of enteric fever and 65 cases of diphtheria, under the head of in patient payments there is £233, most if not all of which, must be presumed to come from the Asylums Board, but if all the infectious cases had been paid for the amount should have been about £1097—a valuable set-off against the £2650 required for rates and taxes.

I am, Sirs, yours faithfully,

Devonshire-place W Jan 16th 1903 WALTER EDMUNDS

THE NOMENCLATURE OF MALARIA.

To the Editors of THE LANCET

SIRS,—It will interest Lieutenant-Colonel D Bruce to know that at the malarial conference held at Nagpur C.P., Christmas, 1901, resolutions similar in spirit to his proposals were passed by the members there present. The first resolution was to the effect that the classification of malarial fevers should be based where possible on a microscopical differentiation of the parasites. The limitation "where possible" was agreed to by some, including myself, with reluctance, although we fully realised that the doctor babu or hospital assistant, or even the village chowkidar, was responsible for a considerable portion of the figures that make up the Serbonian bog of Indian 'fever" statistics The conference was further almost unanimous that the term "malarial cachexia" should be reintroduced into the classification and a resolution to that effect was, I believe, forwarded to those responsible for the present nomenclature of ague or remittent fever Lieutenant S R. Christophers, I.M.S., ployed at the Mond nickel works at Clydach, near nsea, died from what appeared to be the effects of soning by some obscure substance given off during the cesses on which they were engaged. Both men were for several days before their death, and their symptoms e similar to those exhibited by other men who had been cked in the previous months but who had recovered. e most prominent features in all the cases were headache, diness, high fever and rapid breathing Post-mortem mination in the two fatal cases revealed a fatty and in instance a dilated heart. The Mond Nickel Company s very anxious to ascertain the cause of these fatalities and F W Tunnicliffe of King's College, London, and Mr H G mmer of St. Mary's Hospital were accordingly associated h Dr John Jones, the surgeon to the works, in making ull investigation. These gentlemen were later assisted Dr J F Payne, Dr F W Mott, and Dr Otto hner The conclusions which were arrived at, and which re given to a coroner's jury on Jan. 13th by Dr Tunni-ffe, were that ' death was caused by nickel carbonyl, substance inhaled from the dust given off during ployment, which, although the immediate symptoms of it re transient, caused after a short time degeneration of tain parts of the nervous system,' and that this subnce also in all probability produced a change in the con ion of the blood." Further investigations are being made h regard to the scientific aspect of the question.

[1] THE LANCET Dec. 20th 1902, p 1679

an. 19th.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS.)

The New Principal of the University of Edinburgh.

IR WILLIAM TURNER, President of the General Medical uncil and Professor of Anatomy in the University of nburgh has been appointed Principal of the University place of Sir William Muir

Inter-Universities Conference in Edinburgh.

The annual conference of students' representatives from Universities of Edinburgh, Glasgow, Aberdeen, and Andrews took place in Edinburgh at the end of last week. e conference was held in the hall of the Union and was sided over by the chairman of the students representative ncil of Edinburgh University who welcomed the repre-tatives from the other universities. Sir William Muir was present and extended a warm welcome to the repre-tatives. He stated in the course of his remarks that t was the last University function in which he uld take part before he laid down his office. This ference is the fifteenth which has been held alter ely in the different universities Amongst the motions posed and carried by the conference were some of dical interest One was that a petition should be sent the senatus of each university other than Aberdeen to titute a double final examination in medicine, as is at sent done in Aberdeen, the adoption of this by the versities would be a great boon to the students, for at sent failure means having to spend another year to be content with a college qualification Another tion dealt with the need of reform in the medical rriculum. The main point which made the curriculum satisfactory was the present position of surgery and teria medica. The proposer of this motion did not lerstand how any body of men allowed the curriculum at present arranged to be foisted on to the universities, the fact is this notion is erroneous for there can be no ubt that the place of surgery in the early part of the dical curriculum is a relic or survival of the old apprentice-p days and of the ideas which were then supreme. Now sted interests and conservative sentiment uphold what is ically untenable. Another motion approved of the division the academic year into three sessions or terms. The al motion put on record the opinion of the conference at more attention ought to be devoted to physical train g than is at present done in the universities. Another bject which was mooted, but not discussed, had for its ject the possibility of establishing a universities magazine d of approaching Mr Carnegie to see if he would endow ch an undertaking The conference wisely decided not to scuss this matter as it was not on the billet of business om this it will be seen that there is a growing democratic fluence in the Scottish universities which might become very powerful were it not that the students are only a few years at the universities and are senior students before their opinions on many subjects carry any weight. In this conference they have shown much judgment in the motions they adopted.

Edinburgh University Union Extension Scheme

A large public meeting in support of the Edinburgh University Union extension scheme was held in the M'Ewan Hall on the afternoon of Jan. 13th. The hall was crowded, the galleries being occupied by students who had been granted a half holiday Much disappointment was felt at the absence of the Prime Minister who, as Chancellor of the University, was to have presided over the gathering Mr Balfour's sudden indisposition had, however, made it impossible for him to be present The chair was taken by the Lord Rector, Sir R. B Finlay, K.C, M P, Attorney General for England. He was supported by, among others, Lord Robertson of Forteviot (a former Lord Rector of the University), Lord Kinross, Lord Kinnear, Lord Stormonth Darling, a large number of the professorial staff, and many citizens interested in the scheme. Apologies were read from the Chancellor, from the Principal, Sir William Muir, and others. The Lord Rector who was received with great applause referred with regret to the disappointment they had all received from Mr Balfour's enforced absence that afternoon Their only consolation was that their cause was so good a one that they trusted it would not suffer in consequence. He himself felt that he had perhaps one qualification for speaking on behalf of the Students' Union, that qualification being that he had known the Edinburgh University very well 40 years ago and was therefore pretty well qualified to recognise the enormous stride that had been made in the development of university life, thanks to the foundation of the union which they were there that afternoon to support In his student days the students were very much isolated, there being no collective university organisation for bringing them together In their Scottish universities they had not developed the college system of universities in England and what they had to aim at was the development of a collective university life. This was one of the great features of the union which they had met together for the purpose of supporting and extending The union also played the important part of forming a common meeting place for students of arts and medicine who in former days saw very little of each other The union had achieved a great success, but much remained still to be done, and if it had not been for its success in the past they would not be met there that day with the feeling that it was imperative in the interests of the University to do what in them lay to promote the extension of the union. The debating hall he considered a part of the building which could hardly be improved upon It was such as some senates might almost envy The University debates were to his mind a great feature of the life which the union promoted Extension was needed in the dining room, in the library and in the facilities for outdoor and indoor recreation The opportunity now presented itself for having those changes made They had the option of getting the ground required for the additional buildings and he trusted that in the near future they would be able to announce to the students of Edinburgh that they were at last in possession of a union adequately fulfilling all their requirements Lord Robertson who was cordially received, then read a motion in which the meeting pledged itself to do all in its power to assist in raising the necessary funds for the extension of the union. In subsequent remarks he dwelt specially on the value of the union as a social and educative centre for the students outside their classes and he struck an important note when he reminded them that as it was one of the honours of the University that there would be always a large number of poor men among the students any institution which was to reap the best and most complete thought of the University should do nothing which would make it difficult for a poor man to resort to the union. There would be, he was sure such a standard of living and such ideas of industry and of conduct as would not detract from but would merely develop and give fuller play to the old ideas that had done so much for the University The motion, which was seconded by the President of the Students Union, was put to the meeting and was carried by acclamation. An acting committee was then appointed. After a vote of thanks to Sir Robert were *statements* a short time ago that plague had broken out in Delhi there is no available information that it has as yet developed to any serious extent. There has not been any anxiety about the camp because even if introduced there it is not at all likely to spread We shall probably hear of it again in the city before long

The honours bestowed on Major Ross by a foreign Government have been noticed by the press in India and comment is made upon the absence of any recognition while on service in India It is also recalled that Major Freyer and Colonel Keegan who have so distinguished themselves on the surgery of the bladder, more especially for stone, likewise passed out of the service without notice.

Jan 2nd

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT)

Cancer Investigation

THE investigation into the origin and the cure of cancer is, thanks to the munificence of Mr T Sutton Timmis to become an important branch of local scientific pursuit That gentleman has vested in trustees a sum of £10,000 to initiate *systematic research*, which will be carried out at the Liverpool Royal Infirmary (according to the wish of Mr Timmis who is the President of the Royal Infirmary) and the new laboratories of experimental medicine at University College. The trustees of the fund are Mr H Wade Deacon and Mr Henry Timmis The committee which will carry out all the scientific arrangements consists of Dr James Barr, Dr William Carter, Mr F T Paul, Professor Rubert W Boyce, F R.S , Professor C S Sherrington, F R.S , together with the senior physician and the senior surgeon of the Royal Infirmary for the time being as members *ex officio*

Small-pox in Liverpool and its Neighbourhood.

The report of the medical officer of health of Liverpool showed that during the week ending Jan. 10th there were under treatment in the city hospitals 245 cases of small pox and that 59 cases had been reported during the week, as against 48 in the previous week. There were six fatal cases during the week. During the current week, I am informed, there is a slight diminution in the number of fresh cases notified. *The three cases of small* pox which occurred at St Helens on Jan 17th have been closely followed by one at the other side of the borough—viz., Thatto Heath. A collier working at the Sutton Heath Colliery was found on the 19th to be suffering from the disease in an advanced stage. This makes the eleventh case in St. Helens district Two of the earlier patients will be discharged from hospital this week

Memorial to the late Chairman of the David Lewis Northern Hospital

A series of beautiful pictures illustrating sacred subjects, which has been placed in the reredos of the chapel in the David Lewis Northern Hospital in memory of the late Mr J E Sheppard, for 16 years chairman of the hospital, was unveiled on Jan. 8th in the presence of a distinguished company References were made to the many excellent qualities of the deceased gentleman. The memorial has been provided by the committee, medical staff, and friends of the hospital.

Liverpool Country Hospital for Chronic Diseases of Children.

An interesting entertainment, arranged by the Misses Holt of Alexandra Drive, took place on the evening of Dec. 30th, 1902, at the Church Hall, Ullet-road, when an excellent dramatic recital was given by Mr John Harwood of Manchester in aid of the Country Hospital for Chronic Diseases of Children, now in course of erection at Heswall. Mr R. D Holt, the father of the Liberal candidate for the Parliamentary vacancy in the West Derby division of Liverpool, presided over a large and appreciative audience. At the close of the entertainment "free-will offerings" were invited, to which there was a generous response, and a pretty feature on the occasion was the collection by 12 young children each wearing a favour of pale blue ribbon and white heather Miss E. G Holt and Mr Andrew Gibson have contributed £500 each in aid of the building fund.

Jan 20th

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Mumbles Oyster Beds.

A GREAT deal of indignation is being expressed by the members of the Oystermouth district council, within whose area of administration are situated the celebrated Mumbles oyster beds, at the report submitted to the Worshipful Company of Fishmongers by Dr Klein upon the Mumbles oysters Dr Klein in his report stated that half of the oysters examined contained bacillus coli communis and one out of six *contained spores* of bacillus enteritidis and he concluded, therefore, that there was sewage pollution, but only to a limited extent. The sewage from the Oystermouth district is discharged into the sea about 200 yards beyond the oyster beds and it has been proposed that the outfall should be carried out still further, although, as the population of the district is less than 5000, *the safest and most practicable plan* would appear to be to treat the sewage on land and to discharge the effluent into the sea. At a special meeting of the Glamorgan sea fisheries board a disposition was shown to dispute the accuracy of Dr Klein's conclusions, one member even hinting that it was to the interest of the Fishmongers' Company who are large oyster planters, to pollute the samples examined "Some one," he said, 'might have dipped the oysters into a sewer for all they knew" The interests of the district are not likely to be served but by such utterances as this. Further bacteriological examinations are now being made independently by the Board of [illegible] and by the Glamorgan sea fisheries board.

Examination of Water supplies

Although it is no part of their duties as prescribed by the Local Government Board many medical officers of health in rural districts are expected to make an analytical examination of samples of water sent to them for the purpose. As no special payment is made for this additional labour *it is hardly to be expected* that a [illegible] detailed examination can be made and the experience of a medical officer of health in a rural district of Somersetshire may serve as a warning to those medical officers of health who in the past have made preliminary analyses of samples of water procured from supplies within their districts A water which this gentleman had analysed and had found to be free from the impurities ordinarily found in polluted samples was subsequently submitted by the county analyst to a more extended examination and was found to contain strychnine and traces of arsenic suggestive in the opinion of the analyst of rat poison.

Notification of Measles

The Pontypool rural district council has *added* measles to the list of diseases compulsorily notifiable within the district the addition to remain in force for at least five years—a condition insisted upon by the Local Government Board, the period in the opinion of the Board being necessary to allow a fair time to judge of the results

Newport Workmen's Hospital Fund

A sum of over £1200 was subscribed last year to the Newport and County Hospital through the weekly collections of the workmen in the town of Newport

Bristol University College Colston Society

The annual dinner of this society was held on Jan. 13th *under the presidency of the* Bishop of Bristol. There was a large gathering, including Sir J Crichton Browne who was the guest of the evening and *delivered an* interesting speech in the course of which he alluded to the pressing need there was for Bristol to take up the movement for initiating a university for the west of England with its seat at Bristol The collection amounted to £374

Medicine or Refreshment?

The recorder of Bristol had a somewhat curious point to decide on Jan. 10th A refreshment-house keeper had been fined by the bench of magistrates for selling refreshments after 11 P M The "refreshments" consisted of "sarsaparilla and dandelion stout," which the defendant contended were medicinal compounds. The recorder upheld the conviction.

Nickel Carbonyl Poisoning

During the first week of December last two workmen

PARIS

(FROM OUR OWN CORRESPONDENT)

Medicine at a Discount.

THE increasing difficulty which a present-day medical man periences in making a living by the exercise of his profession ds expression in concessions which are not only regrettable t are also seriously compromising to the dignity of that ofession The council of the Syndicate of Medical Men the Department of the Seine has just been consider g certain circulars sent out by some newly qualified dical practitioners which have been distributed to tain families in well to-do circumstances living within said practitioners' sphere of work These circulars offer dical attendance on a whole family by contract, the arly subscription being very small. The council of the ndicate decided that such practice was both culpable and ngerous and resolved that the said practitioners should be mmoned before the syndicate and that the president ould endeavour to make them understand the gravity their position This procedure is, unfortunately the only e in the power of the syndicate to carry out At Tarbes the endly societies, encouraged by the Government which nsiders that their action is a moderate and practical rm of Socialism, have increased to about 20 in number d include a quarter of the whole population, the maining three-quarters of the inhabitants being classed as digents. These friendly societies succeeded in imposing the medical men of Tarbes, whose only paying patients ey were, the condition that they should attend a family r 10 francs per annum, exclusively of major operations and idwifery cases. At the beginning of the year however, the iendly societies made a further stride and reduced the pay eight francs per family per annum, to include major erations and midwifery Thereupon the medical men of arbes unanimously struck and the friendly societies imorted from Toulouse two newly qualified medical men who st no time in accepting the reduced pay These two ractitioners now look after the health of the whole town of arbes—that is to say, so far as regards paying patients hile the other medical men see no one but gratuitous atients. There are, however, two exceptions—namely, the edical officers to the arsenal who receive 2400 francs each er annum from the War Office. But, encouraged by the xample of the people of Tarbes, the director of the arsenal et about revising the annual payment of his medical officers nd put the post up to auction, so to speak. The two actual olders of the post stood out for the old salary, while the two oung practitioners from Toulouse tendered their acceptance f the post at 1200 francs per annum, an offer which the uthorities promptly accepted. The Tarbes syndicate of edical men thereupon sent in a protest to the Minister of Var but most probably they will gain nothing by this action.

Further Results of the Workmen's Compensation Act

I have at various times given your readers some account of he working of the Workmen's Compensation Act which nakes the employer responsible for accidents sustained by a vorkman in the course of his employment and obliges him to rovide medical aid at his own cost. A new point has ecently arisen—namely, when a workman refuses medical id. Sundry decisions have been given by the courts on this oint, as, for instance, the following The court of Rennes has ecided that if a workman refuses medical aid and finds himself thereby incapacitated, the employer is released from any obligation to repair the wrong which the workman has inflicted on himself. The court of Amiens has refused to adjudge a pension to an injured workman who refused medical aid, but has simply allotted him an indemnity for temporary disablement. The court considered that his permanent disablement was due entirely to his refusal to submit to measures which the medical men considered would have completely cured him. Other courts have adjudicated on cases in which a workman refused to submit to an operation which would have enabled him to do at least some work The court of Besançon has decided that if a workman upon whom an operation had been performed refuses to allow any further treatment which would be neither dangerous nor productive of pain he cannot hold his employer responsible for any complications which may arise The court of Aix has decided that a workman is within his rights in refusing to submit to an operation, even a slight one, which it is considered necessary to perform for his cure or relief, but that in such case the employer cannot be held responsible for any complications which may arise. The employer in such case is only to be held responsible for the actual wound, and the court in such cases has only awarded the workman a pension on the very lowest scale.

Obituary

Dr Henri Varnier recently died at the early age of 43 years. Born at Epernay in 1859, he became *interne* in 1882, *chef de clinique* in 1891, *agregé* in 1892, and obstetric physician to the hospitals in 1894 He succeeded in attracting the notice of Pinard, who besides admiring his work had for him a warm personal friendship and who gave him a great deal of work at the Baudelocque clinic. Varnier wrote much , his chief works, besides his thesis for the degree of Doctor the subject of which was "The Musculature of the Inferior Pelvic Strait from an Obstetrical Point of View," were the following—' An Introduction to the Clinical Study and Practice of Labour," written in collaboration with Professor Farabœuf" , "*Every day Obstetrics*" (*Obstétrique Journalière*) , " Studies in Normal and Pathological Obstetrical Anatomy," written in collaboration with Pinard , an ' Anatomical Study on Vicious Implantation of the *Placenta*," written in collaboration with Champetier de Ribes , numerous papers on Symphysiotomy , and Researches on Radiography as applied to Obstetrics For 13 years Dr Varnier directed the *Annales de Gynécologie*, on which publication he succeeded Pinard as editor of the obstetrical department. For many years, too, he wrote all the obstetrical articles in the *Revue Pratique d Obstétrique et Pédiatrie* which he himself founded in 1888.

Jan. 20th

EGYPT

(FROM OUR OWN CORRESPONDENT.)

The Medical Congress the Anatomical Museum.

ONE of the most successful items of the Medical Congress at Cairo was the collection of human remains which have recently been arranged by Dr G Elliot Smith who is working in conjunction with others for the University of California and the Egyptian Medical School. The remains date from the earliest known pre-historic times and must therefore be more than 7000 years old, and side by side with them can now be seen human relics from all the most important dynasties of Egyptian history together with Roman, Ptolemaic, Coptic, and other mummies, until we reach the modern preparations taken from the dissecting room of to-day Of these it is only natural that the greatest interest should centre round the specimens of pre-historic man. They were buried in the sand in the neighbourhood of Girgheh in Upper Egypt, without any attempt at mummifying They lie now in glass cases crouched on the left side with knees bent, preserved to us only by having been buried in dry sand. The men were buried with goat-skin aprons tied round their waists with rope and many of the women have long, curly brown hair No great anatomical differences from men of our own time have yet been discovered, but the skull was distinctly a small one, having an internal capacity of one litre, which compares unfavourably with the one and a half litres of the modern Egyptian peasant's skull or with the usual European skull of two litres.

It will take a year or two to study the anatomical peculiarities, but it appears at first sight that the prehistoric sacrum resembles that of the gorilla rather than that of man. The collection is made more interesting by photographs taken *in situ* of the cemetery and of many of the bodies lying huddled up together before removal Dr Reissner is still working on the spot and has some 70 additional graves to examine during this winter The men and women seem to have been buried together and most of the graves have been plundered in bygone times in order to steal ornaments, especially from the women. Many of the latter have been decapitated in order to remove the ivory ring which they wore round their necks. Some of the soft parts can be seen with the greatest ease. The shrunken brains lying within the skulls still show well marked convolutions, the eyes of many have been preserved, and the lens in some eyes can be distinctly seen, probably due to senile cataract. Dr Smith has been able to demonstrate instances of the subclavian artery, diaphragm, larynx, trachea, and bronchi, sigmoid flexure of the colon, false ligaments of the bladder sacral plexus, &c Many of the intestines contain lumps of fæces which could easily be recognised and

Finlay the proceedings terminated Tea was served in the union at the close of the meeting

Small-pox in Leith

Two cases of small pox are reported as having occurred in Leith. The infected persons are a seaman and a fireman who were engaged on board a steamer which arrived from Riga on Jan. 13th The circumstances connected with the outbreak are that at Riga one of the crew was landed and taken to hospital as he was believed to have small pox. Two days later the authorities said that he was suffering from chicken pox and he was allowed to return to his ship Another of the crew became ill and went to his own home in Leith where he was seen by a medical man who reported him to the medical officer of health as a suspected case of small pox. The sick man was at once removed to the small pox hospital and the medical officer of health visited the steamer and found the man who had been seized at Riga at work on the ship and also learned that he had been engaged in discharging the steamer's cargo This first patient was also removed to the small pox hospital but if he continued to be infective it is impossible to calculate the possible harm that may have been done in the meanwhile Those who have been in contact with the two men have been either isolated or are under medical supervision

Aberdeen University Medical Society

At a meeting of this society on Jan 16th Mr G Grant Macdonald, M A., read a paper on Conservatism in Surgery Mr F Hernaman-Johnson followed with a paper on the Pros and Cons of Vivisection. Both papers were most interesting and were awarded hearty votes of thanks

The Notification of Measles and Whooping cough in Aberdeen

The public health committee of Aberdeen town council has recommended the discontinuance of notifying measles and whooping cough. 1100 cases were notified last month, and it considered that £400 thus annually paid to medical men might be more beneficially expended Dr Matthew Hay in his report stated that during the past ten years measles and whooping cough have caused 1451 deaths in Aberdeen, while during the same period the total deaths from the whole of the other principal zymotic diseases have amounted to 671, any step which might affect the great mortality from measles and whooping cough demanded the fullest and most serious consideration.

Dr C D F Phillips has resigned the assistant examinership in materia medica at Aberdeen University owing to ill health.

Jan 20th

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Public Health of Dublin.

A NEW case of small pox has appeared in the Hardwicke Hospital whence the patient who imported the disease from Liverpool was removed for treatment. The matter seems to be rather serious on account of the congested condition of that part of the city and of the proximity of large public institutions such as the Richmond Surgical Hospital and the Richmond Lunatic Asylum. On Jan. 10th another meeting of the public health committee was held under the presidency of the Lord Mayor to fix a site for the long-deferred isolation hospital After considering the local opposition to several proposals the committee made no selection but decided that if another urgent case of small pox presented itself the patient should be isolated at the Pigeon House· Sir Charles Cameron is reported to have said that he thought it improbable that any outbreak of small pox would take place in the city in the immediate future The report of the Cork street Fever Hospital is generally a good index of the health of Dublin as regards zymotic disease The committee met on Jan. 8th and the registrar's report is not very satisfactory It stated that the admissions were very high owing to the continued prevalence of scarlet fever and diphtheria, which diseases were of a severe type. Several cases of typhus fever were admitted, being in excess of any previous month for several years. Enteric fever shows continued abatement in numbers and severity The measles epidemic has nearly entirely ceased.

Dublin University Biological Association

At the opening meeting of the Dublin University Biological Association the incoming president, Dr T P C Fitzpatrick, chose as the subject of his address the Public Health Control of Consumption, and described the measures for checking the spread of the disease which have been adopted with very good results in Manchester and in New York. Sir John W Moore proposed that the best thanks of the association be accorded to the President for his address and in the course of his speech remarked that he himself did not agree with the Dublin authorities—that it was not possible to have separate wards for the treatment of consumption in general hospitals Sir Charles A. Cameron C B, in seconding the motion, pointed out that the public health committee was in favour of compulsory notification, but that the corporation itself opposed it

The Incorporated Orthopædic Hospital of Ireland.

The annual meeting of the friends and supporters of the Incorporated Orthopædic Hospital of Ireland was held on Jan. 14th in the hospital premises, Great Brunswick street, Lord Justice Walker being in the chair. It was announced that much larger and more suitable premises for the hospital had recently been acquired in Upper Merrion street at a cost of considerably more than £2000. It may interest some readers of THE LANCET to note that the house which is about to be transformed into a hospital was until quite recently one of the finest of the old residential mansions of Dublin. It is separated only by one building from the house which is, perhaps, the most famous in Ireland—Mornington House in which the Duke of Wellington was born in 1769 where Lord Cloncurry and Lord Castlereagh lived, and where "Pamela" was staying when her ill-fated husband, Lord Edward Fitzgerald, was arrested

The late Mr James O Shaughnessy, M R C S. Eng, J P., D.L.

Mr James O Shaughnessy, whose death took place in Limerick on Jan 14th in his ninety third year, was long ago a highly popular and respected medical practitioner in that city For the last two generations, however, his name has been known rather as a philanthropist and as a leader in every social project for the advancement of his fellow countrymen. Several local charitable institutions have long benefited by his care and by his open purse. He was the senior of the magistrates of Ireland and a deputy lieutenant, and he had served in the office of high sheriff and on many occasions as foreman of the grand jury of Limerick. His only son, Mr Richard O'Shaughnessy, B L., who represented the borough of Limerick in Parliament for several years, resides in Dublin and is a distinguished graduate and former scholar of the University of Dublin. He is now one of His Majesty's Commissioners of the Irish Board of Public Works.

Derry Lunatic Asylum.

At a special meeting of the committee of management of the Derry Asylum held in Coleraine on Jan 16th it was decided to adopt the report of the subcommittee which was appointed to consider the plans for the proposed new buildings at Gransha. It recommends that two villas for 3[illegible] patients each, a residence for the medical officer, and administrative, sanitation, and cooking buildings, should be erected and furnished with electric lighting, at a cost not exceeding £15,000

The Mater Infirmorum Hospital, Belfast

From the printed statement of the accounts of the Mater Infirmorum Hospital, Belfast, for the year from Nov 1st, 1901, to Oct 31st, 1902, it appears that the receipts (including a sum of £206 14s 3½d, cash overdrawn from the bank) were £4583 12s 6d Last year the overdraft was £300, so that there is a slight financial improvement this year.

Down Lunatic Asylum

In his report of inspection of this asylum Sir G P O'Farrell, inspector of lunatics, says "Each succeeding visit of inspection to this asylum satisfies me more completely of the excellent management of the resident medical superintendent and of the amount of time and thought which he devotes to the efficient and economical working of the institution. The difference between able and careful and lax and inefficient administration of an asylum means a difference of several thousand pounds a year in the cost of management, and it would be difficult to find a stronger proof of this fact than Downpatrick, where the resident medical superintendent, by formulating for his committee and for the county council an economical scheme for providing for the chronic and harmless insane of the district, and by the minute attention which he gives to the details of his duties, has effected a considerable saving to the ratepayers.

During the week marked copies of the following newspapers have been received *Staffordshire Sentinel, Times of India Aberdeen Weekly Free Press, Daily Mail, South Wales Echo, Pioneer Mail (India) Devon and Exeter Express, Dublin Evening Telegraph Echo Bradford Observer Daily Express Globe, Trade Protection Journal Ross Gazette Medical Brief (St Louis U S.A) Knowledge Westminster Gazette Lambeth Mercury Lincoln Herald Windsor and Eton Express Derbyshire Courier Manchester Weekly Chronicle, Derbyshire Times, Yorkshire Mercury Reading Mercury Herts Advertiser Hong-Kong Telegraph, Daily Telegraph, Revue Française de Médecine et de Chirurgie, &c.*

the ethnology will be quite good enough for the class of inquirer like the gentleman who was so disappointed on going to Albania to find that the Albanians had not got pink eyes Lying in a case in the centre of the room was an almost life-sized carefully executed model of a young lady in a frilled chemise undergoing the Cæsarean operation The abdomen and the uterus were opened but the uterus had not contracted All the same its walls were rigid and seated in the interior like a water baby in a shell was a small fœtus of about seven months Passing over such strange diseases as noemus masculaire amicloplaxe tumour and gummatum we were invited upstairs to an inner sanctum to which only adults are admitted Here were shown to adults only the recent and remote effects of syphilis in both sexes the series commencing from the virgin Other exhibits included a forceps delivery a normal confinement and an embryological series of carefully made wax models Another carefully made model was one showing the sympathetic system. On the whole however the exhibition is merely a catch penny appeal to the prurient It cannot be good for all and sundry to be able to see Cæsarean sections even inaccurately represented or models of spermatozoa and the development of the fœtus Even if the upper room is strictly confined to adults we doubt the wisdom of the exhibition It *may* keep both men and women in the straight path to see a phagedænic vulva or penis or a face rotting away, but we doubt it

ZOX.

M R C S has written to us as follows — I enclose a powder which you may not have yet had experience of in your laboratory A patient of mine having taken three such powders one at 6 P.M another at 8 P M and a third at midnight woke his wife about 3 A.M thinking that he was dying He had great depression in the præcordial region, was pale with cold sweats and muscular twitchings. An analysis of these powders called Zox powders might be of service We examined the substance sent to us but not sufficient material reached us to enable us to say definitely which antipyretic or analgesic the powder contained It is very clearly an anilin synthetic either antifebrin or phenacetin but not antipyrin and we need hardly say that its ingestion without medical direction is dangerous. The directions on the box say that one powder can be taken in a cup of anything hot and that [illegible] dose can be repeated in two hours if necessary The patie[illegible] to have followed the instructions on the box

THE PROGRESSIVE MEDIC[illegible]

STITCHES.

gery without Antiseptics

ly materials which can sterilised by heat are ployed, and apparently at trouble is taken in erilising these ligatures Apparently, also, in the practice of many surgeons catgut is entirely given up and the use of silk is diminished as far as possible Indeed, some surgeons instead of employing silk to bring together the edges of the wound have given that up and fix the edges together by metal clamps. The ligatures after removal from the steriliser are placed in salt solution till required.

Limited Use of Antiseptics

On the other hand, we employ catgut for all purposes for which we formerly used it and have no hesitation in burying silk, silkworm gut, &c. Any of these materials which can be disinfected by boiling we disinfect in that way and subsequently keep them till required for use in 1 in 20 carbolic acid solution. As catgut cannot be easily sterilised by boiling, we generally treat it by prolonged immersion in repeated changes of 1 in 20 carbolic lotion. I generally immerse the catgut in pure carbolic acid in the first instance for about 24 hours, and then subsequently in 1 in 20 carbolic lotion. The ligatures, like the instruments, are rinsed in 1 in 2000 sublimate solution before use.

By giving up catgut it seems to me that surgeons have lost one of the most important advances in wound treatment, and I regard the giving up of buried sutures for uniting divided muscles, &c., as an extremely retrograde step Apparently, the reason why catgut was given up was that as suppuration still occurred in the wound and as catgut as it comes into the surgeon's hands is a septic material the suppuration was attributed to the catgut. But as a matter of fact, in my experience there is no real difficulty in the disinfection of catgut, and as regards silk, which is now held to be guilty of many of the septic accidents which occur, I cannot conceive what there is in silk which should make sterilisation more difficult than in the case of swabs, gauze dressings, &c. There is this, however, in silk that explains the difficulty—namely, that if a wound becomes infected the silk, being an inert material and being soaked with putrescible substances, forms a favourable nidus in which the bacteria can multiply and ultimately infect the whole woun On the other hand, a wound which does not contain an t putrescible material may be able in some cases to g of a considerable number of pathogenic organisms d that they are not particularly virulent, and so tl d will heal by first intention. It is not imperfect ation of these materials which is the

the area of operation to the dust which is necessarily raised by their entrance into the operating theatre Elaborate precautions must be taken to avoid any risk of infection during the operation, the surgeon wears a mask and cap to cover his hair, is completely covered with aseptic clothing, he has always the same assistants or, at any rate, assistants who are very largely experienced in these methods, and he is intent on avoiding every possible source of infection from outside In the hands of surgeons who are skilled bacteriologists and who are thoroughly impressed with all the precautions necessary and who have skilled assistants no objection can of course be made to the method employed, if they think that they can obtain better results than they otherwise could My criticism is that the results are not in any way better than those obtained with the limited use of antiseptics, that the precautions necessary are very much more troublesome, the risks of error very much greater, and that as a means of instruction and as a method to be employed by practitioners generally it is totally impracticable. Further, it must be remembered that all practitioners, or even all surgeons, are not skilled bacteriologists and the greater the precautions necessary for carrying out the treatment the greater are the chances of error and the risks of failure. In former days the materials employed, and not the principles and details of the method, were looked on by many as the essential points, and thus Listerism was often spoken of as "carbolic acid treatment," the "spray and gauze method," &c Needless to say, with the neglect of the details and the erroneous and usually very excessive application of antiseptics the hoped-for result—viz, an aseptic wound—was not always obtained. And so at the present time the same mistake is very likely to be made and most stress laid on the external surroundings, on the marble operating room, the beautifully tessellated floors, the absence of corners or angles in the room, the washing basins provided with foot-taps, and so forth, while the real essentials of the treatment—namely, the careful disinfection of the skin and and the avoidance during the operation of any possi- contaminating instruments, ligatures, stitches, the wound itself—tend to be overlooked. And I is the chief reason why we hear of so much th ligatures.

difficulties in the way of success by this method, , are not limited to the surgeon himself, but also ve his assistants and to an even greater extent the nurses. No doubt in some hospitals where this treatment is rigorously carried out the assistants and nurses are very thoroughly trained, but nurses especially, not being skilled in bacteriology, are very liable to error, and, after all, they can only reflect the impression which is produced on the ordinary intelligent mind by the precautions employed and which they have been enjoined to enforce. In many cases, no doubt, one comes across nurses who understand a great deal about the precautions which are required and who have evidently been very carefully drilled. But even these are sometimes apt to commit errors which tend to vitiate the whole procedure For example, if the patient move during the operation the nurse replaces him in the proper position on the table, rearranges the blankets, and without any fresh purification of her hands proceeds to hand swabs, &c Indeed, if she wanted to disinfect her hands again she has in all probability no antiseptic at hand for the purpose. Or an instrument falls on the floor and she picks it up, or the surgeon wishes something out of his bag, and she opens his bag and gets what is required and either forgets or has not the opportunity of disinfecting her hands As a matter of fact, after such an accident, if no antiseptics are present she should take no further part in the operation, but it is seldom possible to dispense with her services. On the other hand, if she were washing sponges out of an antiseptic or had antiseptics in the neighbourhood her hands would be disinfected for her even though she forgot the necessity of doing it. And even the best trained nurses are apt to place too much confidence in the precautions that they take, especially in the boiling of instruments. An instrument falls on the floor, the nurse disinfects it again, she takes it to the steriliser, puts it in for a second or two, and brings it back within the minute, as she says, sterilised. It has not been drilled into her that sterilisation cannot be accomplished at this lightning speed. And very likely the steriliser was in another room and she has to turn the handle of the door and touch various articles which have not been disinfected before she comes back, and then she has no facilities for disinfection of her hands again And so I could go on enumerating many sources of infection which may seem trivial but are nevertheless essential to a certain result and where the absence of antiseptics completely handicaps those engaged in the operation But, on the other hand, many nurses who come from so called "aseptic" hospitals have evidently been very imperfectly drilled, and indeed have not the faintest glimmering of what asepsis really means, and one is constantly in peril of employing dressings, swabs, &c., which have not been properly sterilised. I need not take up space in enumerating these grosser errors, they strike the eye at once. It is very common to find that the nurse has spent no end of time and trouble in preparing a basin full of rolls of beautifully white wool with or without some gauze around them, but has not sterilised them in any way, indeed, has not realised that they needed to be sterilised as they are made of "medicated" cotton-wool. She will also have probably got in various antiseptic dressings, opened the packets, cut them into beautiful squares, and wrapped them all up in a clean but not sterilised towel along with bandages, medicated cotton wool, &c. To sterilise the skin one will probably be presented with a basin containing a boiled nail brush, soap, and boiled water, but no antiseptic, or if one asks for, say, carbolic acid a dash of 1 in 20 is put into the water Indeed, the mixture of asepsis and sepsis is most ludicrous, but, at the same time, extremely dangerous. That errors of this kind can be committed and that the nurse is nevertheless perfectly satisfied that she is contributing to the asepsis of an operation is an example of the impression made on many untrained minds with regard to the precautions necessary to carry out this treatment.

While, therefore, as I said at the commencement, the method is one with which I have no fault to find in theory or if carried out by a trained bacteriologist it is not one which I think can by any possibility be recommended for general use, and I do not think that students, who will not necessarily have all the arrangements at hand in after life, should be instructed in it as the only or chief method which they should employ As a matter of fact, for the proper carrying-out of asepsis without antiseptics a regular institution is required and assistants and nurses who have been long trained in the methods are necessary In our hospitals, where we are constantly changing our house surgeons, dressers, and nurses, the difficulties in the way of obtaining constant success are very great and unless in the hands of a few who are earnestly impressed with the precautions necessary constant success is practically unattainable. In private work the conditions are still more difficult. As a matter of fact, operations in private houses without antiseptics are hardly practicable and they must involve the taking of the same assistant and the same nurse to all cases No doubt if this sort of treatment is really necessary nothing further can be said than that everyone must try to carry it out, but it is not really necessary, because those who employ antiseptics in a limited manner on the Listerian principles obtain equally good results—indeed, I venture to assert, more constant results, and one cannot get better results than rapid and constant union by first intention without any local or general disturbance. For my own part I take a very pessimistic view of the present state of matters with regard to wound treatment and I believe that if this so-called aseptic treatment is continued a time will come when the frequency of sepsis in wounds will be very considerable, and when the thoroughness that is characteristic of surgery at the present time will become diminished, as, indeed, is already happening in various ways, such as the careful stitching up of the deeper parts of abdominal wounds. On the other hand, the intelligent use of antiseptics saves a great deal of trouble, makes the result more certain and does not interfere in any way with the after progress of the wound. If I contrast the methods employed the differences will be seen to be really very slight but at the same time, I venture to think, of very great importance.

DISINFECTION OF THE SKIN

Surgery without Antiseptics and Limited Use of Antiseptics.

This ought to be the same in both cases The actual antiseptics employed, the length of time for which they are allowed to act, and so forth, vary according to the fancy of the surgeon but antiseptics must be used for the purpose. At the same time there is a tendency to less thorough disinfection in the so-called "aseptic" surgery and some surgeons, indeed, are satisfied with violent scrubbing of the skin with a nail brush and clean water without the use of antiseptics. This, of course, at once takes the method out of he region of asepsis. A common error that I find nurses ommit is that the night before the operation the skin is washed with soap and water and then with ether, and then a ine piece of lint very firmly wrung out or 1 in 40 carbolic cid is applied over the skin and left on. It is quite clear hat here there is no disinfection of the skin, the lint is ractically wrung dry and there is no carbolic acid to come n contact with the skin.

Disinfection of Instruments.

Surgery without Antiseptics	*Limited use of Antiseptics*
Instruments boiled just efore the operation and laced in sterilised salt soluion till required.	Instruments boiled, placed in 1 in 20 carbolic acid lotion till required Before use the carbolic acid is rinsed away with weak sublimate solution or in the case of abdominal operations with sterilised salt solution.

Disinfection of instruments, &c. by heat instead of by ntiseptics is without doubt a great improvement on former nethods, but when the instruments, ligatures &c., are emoved from the steriliser unless they are kept in an antieptic solution till they are required there is always, specially in hospital work, a risk of their becoming nfected In spite of the fact that the organisms present n the dust floating in the air are essentially non pathogenic, ne must not reckon on that too completely and it is much etter to avoid the introduction as far as possible of any rganisms than to take one's chance that those that do enter re non pathogenic.

Aseptic Area around the Seat of Operation

Surgery without Antiseptics	*Limited Use of Antiseptics*
Towels which have been oiled or steamed are placed round the area of operation. They are practically dry, indeed often completely dry, and contain no antiseptic.	Towels which have been boiled and subsequently placed in 1 in 2000 sublimate solution are lightly wrung out and arranged around the area of operation.

In the two cases the only difference is that in the method which I advocate the towel retains some moist antiseptic, whereas in the other it is absent. The advantage of the ormer in my opinion, is that dust falling on the towel or getting on it from other sources is, at any rate, fixed and may very possibly be disinfected, and also that the hands or nstruments resting on the towels are not so likely to pick up lust. Further, infective material which may have got on to he hands or instruments during the course of the operation nay also become disinfected.

General Precautions during the Operation

Surgery without Antiseptics	*Limited Use of Antiseptics.*
There is no antiseptic material present in which the hands may be re-disinfected should accidental contamination take place. The surgeon must consequently devote extreme attention to the avoidance of any possible contamination of hands or instruments during the course of the operation, and where the operation lasts a long time it is evident that this must entail a very considerable strain and a very considerable possibility of failure	A basin of 1 in 2000 sublimate solution is at hand in which the hands and instruments are rinsed from time to time. In this way accidental contamination is rectified. The few drops of sublimate solution which may enter the wound in these circumstances are quite insignificant and are probably at once completely neutralised by the blood present in the wound, and as a matter of fact do not produce any noticeable irritation.

Sponges.

Surgery without Antiseptics	*Limited Use of Antiseptics.*
Dry swabs which have been steamed or boiled and dried are employed. Here everything depends on the completeness of the sterilisation and on the avoidance of contamination during the operation	If swabs are used they are disinfected by heat and subsequently placed in a 1 in 2000 sublimate solution and wrung out as required. Here the sterilisation is the same, but the risk of contamination during a prolonged operation is diminished from the fact that the sponges are lying in an effective antiseptic solution till required for use.

For my own part I still employ marine sponges. These cannot be boiled, but they can be thoroughly disinfected if kept in carbolic acid (1 in 20) for several days, the solution being changed frequently and then during the operation they are kept in a 1 in 2000 sublimate solution and wrung out as required. I see no reason whatever why marine sponges should not be employed. I presume that they were given up in the first place because they could not be disinfected by heat and in the second place because they were supposed to be the source of contamination which evidently occasionally occurred. One must not, however, get into the habit of thinking that heat is the only possible method of disinfection and practical experience shows that the method which we employ of disinfecting these sponges by prolonged immersion in a strong carbolic acid solution is perfectly satisfactory That being so no one will doubt the advantage of sponges over swabs as a means of removing blood from a wound But apart from the advantages of marine sponges I consider that swabs are really a very considerable source of danger. In the first place, one must be quite sure that they are properly sterilised and unless the surgeon or an assistant whom he can trust does that he is very likely, as I generally am, to be offered swabs which are either not sterilised at all or have been only imperfectly treated. Now, if they are imperfectly sterilised or if any mistake in the bacteriological methods takes place during the operation the swab becomes a source of great danger, because however carefully prepared there is always not only the possibility but the probability of threads of wool being detached from the swab and left behind in the wound. As long as these threads are aseptic they do not matter, but if they become infected they, like the stitches, become sources of irritation and prevent healing

Stitches.

Surgery without Antiseptics	*Limited Use of Antiseptics*
Only materials which can be sterilised by heat are employed, and apparently great trouble is taken in sterilising these ligatures Apparently, also, in the practice of many surgeons catgut is entirely given up and the use of silk is diminished as far as possible Indeed, some surgeons instead of employing silk to bring together the edges of the wound have given that up and fix the edges together by metal clamps. The ligatures after removal from the steriliser are placed in salt solution till required.	On the other hand, we employ catgut for all purposes for which we formerly used it and have no hesitation in burying silk, silkworm gut, &c. Any of these materials which can be disinfected by boiling we disinfect in that way and subsequently keep them till required for use in 1 in 20 carbolic acid solution. As catgut cannot be easily sterilised by boiling, we generally treat it by prolonged immersion in repeated changes of 1 in 20 carbolic lotion. I generally immerse the catgut in pure carbolic acid in the first instance for about 24 hours, and then subsequently in 1 in 20 carbolic lotion. The ligatures, like the instruments, are rinsed in 1 in 2000 sublimate solution before use.

By giving up catgut it seems to me that surgeons have lost one of the most important advances in wound treatment, and I regard the giving up of buried sutures for uniting divided muscles &c., as an extremely retrograde step Apparently, the reason why catgut was given up was that as suppuration still occurred in the wound and as catgut as it comes into the surgeon's hands is a septic material the suppuration was attributed to the catgut. But as a matter of fact, in my experience there is no real difficulty in the disinfection of catgut, and as regards silk, which is now held to be guilty of many of the septic accidents which occur, I cannot conceive what there is in silk which should make sterilisation more difficult than in the case of swabs, gauze dressings, &c. There is this, however, in silk that explains the difficulty—namely, that if a wound becomes infected the silk, being an inert material and being soaked with putrescible substances forms a favourable nidus in which the bacteria can multiply and ultimately infect the whole wound. On the other hand, a wound which does not contain any inert putrescible material may be able in some cases to get rid of a considerable number of pathogenic organisms provided that they are not particularly virulent, and so the wound will heal by first intention. It is not imperfect sterilisation of these materials which is the

the area of operation to the dust which is necessarily raised by their entrance into the operating theatre Elaborate precautions must be taken to avoid any risk of infection during the operation, the surgeon wears a mask and cap to cover his hair, is completely covered with aseptic clothing, he has always the same assistants or, at any rate, assistants who are very largely experienced in these methods, and he is intent on avoiding every possible source of infection from outside In the hands of surgeons who are skilled bacteriologists and who are thoroughly impressed with all the precautions necessary and who have skilled assistants no objection can of course be made to the method employed, if they think that they can obtain better results than they otherwise could My criticism is that the results are not in any way better than those obtained with the limited use of antiseptics, that the precautions necessary are very much more troublesome, the risks of error very much greater, and that as a means of instruction and as a method to be employed by practitioners generally it is totally impracticable Further, it must be remembered that all practitioners, or even all surgeons, are not skilled bacteriologists and the greater the precautions necessary for carrying out the treatment the greater are the chances of error and the risks of failure. In former days the materials employed, and not the principles and details of the method, were looked on by many as the essential points, and thus Listerism was often spoken of as "carbolic acid treatment," the "spray and gauze method," &c Needless to say, with the neglect of the details and the erroneous and usually very excessive application of antiseptics, the hoped for result—viz, an aseptic wound—was not always obtained And so at the present time the same mistake is very likely to be made and most stress laid on the external surroundings, on the marble operating room, the beautifully tessellated floors, the absence of corners or angles in the room, the washing basins provided with foot-taps, and so forth, while the real essentials of the treatment—namely, the careful disinfection of the skin and hands and the avoidance during the operation of any possibility of contaminating instruments, ligatures, stitches, sponges, or the wound itself—tend to be overlooked. And I believe this is the chief reason why we hear of so much trouble with ligatures

The difficulties in the way of success by this method, however, are not limited to the surgeon himself, but also involve his assistants and to an even greater extent the nurses No doubt in some hospitals where this treatment is rigorously carried out the assistants and nurses are very thoroughly trained, but nurses especially, not being skilled in bacteriology, are very liable to error, and, after all, they can only reflect the impression which is produced on the ordinary intelligent mind by the precautions employed and which they have been enjoined to enforce In many cases, no doubt, one comes across nurses who understand a great deal about the precautions which are required and who have evidently been very carefully drilled. But even these are sometimes apt to commit errors which tend to vitiate the whole procedure. Or an instrument falls on the floor and she picks it up, or the surgeon wishes something out of his bag, and she opens his bag and gets what is required and either forgets or has not the opportunity of disinfecting her hands As a matter of fact, after such an accident, if no antiseptics are present she should take no further part in the operation, but it is seldom possible to dispense with her services On the other hand, if she were washing sponges out of an antiseptic or had antiseptics in the neighbourhood her hands would be disinfected for her even though she forgot the necessity of doing it. And even the best trained nurses are apt to place too much confidence in the precautions that they take, especially in the boiling of instruments An instrument falls on the floor, the nurse disinfects it again, she takes it to the steriliser, puts it in for a second or two, and brings it back within the minute, as she says, sterilised It has not been drilled into her that sterilisation cannot be accomplished at this lightning speed. And very likely the steriliser was in another room and she has to turn the handle of the door and touch various articles which have not been disinfected before she comes back, and then she has no facilities for disinfection of her hands again And so I could go on enumerating many sources of infection which may seem trivial but are nevertheless essential to a certain result and where the absence of antiseptics completely handicaps those engaged in the operation But, on the other hand, many nurses who come from so called "aseptic" hospitals have evidently been very imperfectly drilled, and indeed have not the faintest glimmering of what asepsis really means, and one is constantly in peril of employing dressings, swabs, &c., which have not been properly sterilised. I need not take up space in enumerating these grosser errors, they strike the eye at once. It is very common to find that the nurse has spent no end of time and trouble in preparing a basin full of rolls of beautifully white wool with or without some gauze around them, but has not sterilised them in any way, indeed, has not realised that they needed to be sterilised as they are made of "medicated" cotton-wool She will also have probably got in various antiseptic dressings, opened the packets, cut them into beautiful squares, and wrapped them all up in a clean but not sterilised towel along with bandages, medicated cotton wool, &c. To sterilise the skin one will probably be presented with a basin containing a boiled nail brush, soap, and boiled water, but no antiseptic, or if one asks for, say, carbolic acid a dash of 1 in 20 is put into the water Indeed, the mixture of asepsis and sepsis is most ludicrous, but, at the same time, extremely dangerous That errors of this kind can be committed and that the nurse is nevertheless perfectly satisfied that she is contributing to the asepsis of an operation is an example of the impression made on many untrained minds with regard to the precautions necessary to carry out this treatment.

While, therefore, as I said at the commencement, the method is one with which I have no fault to find in theory or if carried out by a trained bacteriologist it is not one which I think can by any possibility be recommended for general use, and I do not think that students, who will not necessarily have all the arrangements at hand in after life, should be instructed in it as the only or chief method which they should employ As a matter of fact, for the proper carrying-out of asepsis without antiseptics a regular institution is required and assistants and nurses who have been long trained in the methods are necessary In our hospitals, where we are constantly changing our house surgeons, dressers, and nurses, the difficulties in the way of obtaining constant success are very great and unless in the hands of a few who are earnestly impressed with the precautions necessary constant success is practically unattainable. In private work the conditions are still more difficult. As a matter of fact, operations in private houses without antiseptics are hardly practicable and they must involve the taking of the same assistant and the same nurse to all cases No doubt if this sort of treatment is really necessary nothing further can be said than that everyone must try to carry it out, but it is not really necessary, because those who employ antiseptics in a limited manner on the Listerian principles obtain equally good results—indeed, I venture to assert, more constant results, and one cannot get better results than rapid and constant union by first intention without any local or general disturbance. For my own part I take a very pessimistic view of the present state of matters with regard to wound treatment and I believe that if this so-called aseptic treatment is continued a time will come when the frequency of sepsis in wounds will be very considerable, and when the thoroughness that is characteristic of surgery at the present time will become diminished, as, indeed, is already happening in various ways, such as the careful stitching up of the deeper parts of abdominal wounds. On the other hand, the intelligent use of antiseptics saves a great deal of trouble, makes the result more certain, and does not interfere in any way with the after progress of the wound. If I contrast the methods employed the differences will be seen to be really very slight but at the same time, I venture to think, of very great importance.

DISINFECTION OF THE SKIN

Surgery without Antiseptics and Limited Use of Antiseptics.

This ought to be the same in both cases The actual antiseptics employed, the length of time for which they are allowed to act, and so forth, vary according to the fancy of the surgeon but antiseptics must be used for the purpose. At the same time there is a tendency to less thorough disinfection in the so-called "aseptic" surgery and some surgeons, indeed, are satisfied with violent scrubbing of the skin with a nail brush and clean water without the use of antiseptics. This, of course, at once takes the method out of the region of asepsis. A common error that I find nurses commit is that the night before the operation the skin is washed with soap and water and then with ether, and then a fine piece of lint very firmly wrung out of 1 in 40 carbolic acid is applied over the skin and left on. It is quite clear that here there is no disinfection of the skin; the lint is practically wrung dry and there is no carbolic acid to come in contact with the skin.

DISINFECTION OF INSTRUMENTS.

Surgery without Antiseptics.	*Limited use of Antiseptics.*
Instruments boiled just before the operation and placed in sterilised salt solution till required.	Instruments boiled, placed in 1 in 20 carbolic acid lotion till required. Before use the carbolic acid is rinsed away with weak sublimate solution or in the case of abdominal operations with sterilised salt solution.

Disinfection of instruments, &c., by heat instead of by antiseptics is without doubt a great improvement on former methods, but when the instruments, ligatures, &c., are removed from the steriliser unless they are kept in an antiseptic solution till they are required there is always, especially in hospital work, a risk of their becoming infected. In spite of the fact that the organisms present in the dust floating in the air are essentially non-pathogenic, one must not reckon on that too completely and it is much better to avoid the introduction as far as possible of any organisms than to take one's chance that those that do enter are non-pathogenic.

ASEPTIC AREA AROUND THE SEAT OF OPERATION.

Surgery without Antiseptics.	*Limited Use of Antiseptics.*
Towels which have been boiled or steamed are placed around the area of operation. They are practically dry, indeed often completely dry, and contain no antiseptic.	Towels which have been boiled and subsequently placed in 1 in 2000 sublimate solution are lightly wrung out and arranged around the area of operation.

In the two cases the only difference is that in the method which I advocate the towel retains some moist antiseptic, whereas in the other it is absent. The advantage of the former in my opinion, is that dust falling on the towel or getting on it from other sources is, at any rate, fixed and may very possibly be disinfected, and also that the hands or instruments resting on the towels are not so likely to pick up dust. Further, infective material which may have got on to the hands or instruments during the course of the operation may also become disinfected.

GENERAL PRECAUTIONS DURING THE OPERATION.

Surgery without Antiseptics.	*Limited Use of Antiseptics.*
There is no antiseptic material present in which the hands may be re-disinfected should accidental contamination take place. The surgeon must consequently devote extreme attention to the avoidance of any possible contamination of hands or instruments during the course of the operation, and where the operation lasts a long time it is evident that this must entail a very considerable strain and a very considerable possibility of failure.	A basin of 1 in 2000 sublimate solution is at hand in which the hands and instruments are rinsed from time to time. In this way accidental contamination is rectified. The few drops of sublimate solution which may enter the wound in these circumstances are quite insignificant and are probably at once completely neutralised by the blood present in the wound, and as a matter of fact do not produce any noticeable irritation.

SPONGES.

Surgery without Antiseptics.	*Limited Use of Antiseptics.*
Dry swabs which have been steamed or boiled and dried are employed. Here everything depends on the completeness of the sterilisation and on the avoidance of contamination during the operation.	If swabs are used they are disinfected by heat and subsequently placed in a 1 in 2000 sublimate solution and wrung out as required. Here the sterilisation is the same, but the risk of contamination during a prolonged operation is diminished from the fact that the sponges are lying in an effective antiseptic solution till required for use.

For my own part I still employ marine sponges. These cannot be boiled, but they can be thoroughly disinfected if kept in carbolic acid (1 in 20) for several days, the solution being changed frequently and then during the operation they are kept in a 1 in 2000 sublimate solution and wrung out as required. I see no reason whatever why marine sponges should not be employed. I presume that they were given up in the first place because they could not be disinfected by heat and in the second place because they were supposed to be the source of contamination which evidently occasionally occurred. One must not, however, get into the habit of thinking that heat is the only possible method of disinfection and practical experience shows that the method which we employ of disinfecting these sponges by prolonged immersion in a strong carbolic acid solution is perfectly satisfactory. That being so no one will doubt the advantage of sponges over swabs as a means of removing blood from a wound. But apart from the advantages of marine sponges I consider that swabs are really a very considerable source of danger. In the first place, one must be quite sure that they are properly sterilised and unless the surgeon or an assistant whom he can trust does that he is very likely, as I generally am, to be offered swabs which are either not sterilised at all or have been only imperfectly treated. Now, if they are imperfectly sterilised or if any mistake in the bacteriological methods takes place during the operation the swab becomes a source of great danger, because however carefully prepared there is always not only the possibility but the probability of threads of wool being detached from the swab and left behind in the wound. As long as these threads are aseptic they do not matter, but if they become infected they, like the stitches, become sources of irritation and prevent healing.

STITCHES.

Surgery without Antiseptics.	*Limited Use of Antiseptics.*
Only materials which can be sterilised by heat are employed, and apparently great trouble is taken in sterilising these ligatures. Apparently also, in the practice of many surgeons catgut is entirely given up and the use of silk is diminished as far as possible. Indeed, some surgeons instead of employing silk to bring together the edges of the wound have given that up and fix the edges together by metal clamps. The ligatures after removal from the steriliser are placed in salt solution till required.	On the other hand, we employ catgut for all purposes for which we formerly used it and have no hesitation in burying silk, silkworm gut, &c. Any of these materials which can be disinfected by boiling we disinfect in that way and subsequently keep them till required for use in 1 in 20 carbolic acid solution. As catgut cannot be easily sterilised by boiling, we generally treat it by prolonged immersion in repeated changes of 1 in 20 carbolic lotion. I generally immerse the catgut in pure carbolic acid in the first instance for about 24 hours, and then subsequently in 1 in 20 carbolic lotion. The ligatures, like the instruments, are rinsed in 1 in 2000 sublimate solution before use.

By giving up catgut it seems to me that surgeons have lost one of the most important advances in wound treatment, and I regard the giving up of buried sutures for uniting divided muscles, &c., as an extremely retrograde step. Apparently, the reason why catgut was given up was that as suppuration still occurred in the wound and as catgut as it comes into the surgeon's hands is a septic material the suppuration was attributed to the catgut. But as a matter of fact, in my experience there is no real difficulty in the disinfection of catgut; and as regards silk, which is now held to be guilty of many of the septic accidents which occur, I cannot conceive what there is in silk which should make sterilisation more difficult than in the case of swabs, gauze dressings, &c. There is this however, in silk that explains the difficulty—namely, that if a wound becomes infected the silk, being an inert material and being soaked with putrescible substances, forms a favourable nidus in which the bacteria can multiply and ultimately infect the whole wound. On the other hand, a wound which does not contain any inert putrescible material may be able in some cases to get rid of a considerable number of pathogenic organisms provided that they are not particularly virulent, and so the wound will heal by first intention. It is not imperfect sterilisation of these materials which is the trouble—it is that they are present in a wound to which bacteria have been admitted by the employment of imperfect bacteriological methods

DRAINAGE OF THE WOUNDS

Surgery without Antiseptics	*Limited Use of Antiseptics*
No drainage is required unless in exceptional circumstances. Then what are called gauze wicks, little twisted pieces of gauze, are left in the wound.	No drainage is required unless in exceptional circumstances. In that case the use of a suitably sized drainage-tube is most efficacious
